The Essex Design Guide for Residential and Mixed Use Areas

Essex Planning Officers Association
The projected increase in the number of households over the next twenty years is likely to lead to a significant amount of new housing development on both greenfield and brownfield sites in Essex. As this new development will have a considerable impact on both town and country and constitute a sizeable new slice of urban fabric, it is important that we get it right.

Unfortunately, much recent new housing development has concentrated on producing houses as consumer products with little or no attention paid to the quality of the environment that results. The consequence is that residents feel no allegiance to the locality and seek to move on as quickly as possible. Local authorities in Essex wish to see the creation of stable communities based on local services and therefore I welcome the appearance of this Guide which demonstrates how, by employing best practice, it is possible to create new places of quality and identity where people will want to stay.

By setting out criteria, it is hoped to reduce the degree of uncertainty for the developer and ease negotiations with the planning authority. At the same time, by locating development in the right places and laying it out for ease of access by walking, cycling and public transport rather than traffic circulation, it is our intention that new development should underpin the environmental sustainability of the settlement pattern in Essex rather than undermine it.

Peter Croft  DipTP MRTPi
Chairman, Essex Planning Officers Association.
October 1997
Public Consultations

This Guide was advertised and available on deposit at Branch Libraries and District Council offices throughout Essex during September 1997.

An earlier draft was circulated for technical consultation in 1996 to a large number of bodies including:

- Planning and highways departments of all local authorities in Essex
- Planning departments of all local authorities bordering Essex
- The Department of the Environment
- The Department of Transport
- The Government Office for the Eastern Region
- The Prince of Wales Institute of Architecture
- National Joint Utilities Group
- Essex Chapters of the Royal Institute of British Architects
- Royal Town Planning Institute
- National House Building Council
- House Builders’ Federation, South-East and London Regions
- Council for the Protection of Rural Essex
- Civic Trust
- John Noble (author of Design Bulletin 32)
- Royal Institute of Chartered Surveyors, Eastern Region
- National Federation of Housing Associations
- Urban Design Group
- Town and Country Planning Association
- Association of County and District Councils
- Planning Officers’ Association
- Essex County Police
- Essex Fire and Rescue Service
- Essex Building Surveyors Association
- Access Committee for England
- Essex Access Forum
- Anglia Polytechnic University
- Oxford Brookes University
- University of the South Bank
- Liverpool University
- English Nature
- Various housebuilding firms and architectural practices active in Essex

In 1997 this Guide was the subject of an Essex County Council Safety Audit and checked for compliance with the County Council’s Travelwise, Pedestrian and Mobility policies.

The Essex Design Guide for Residential Areas first appeared in 1973, published by Essex County Council, and has been used in development control in Essex over the ensuing period. When first published, it was envisaged that the Guide would be implemented by the County Council as planning authority, but the reorganisation of local government in 1974 resulted in its principles being applied as Supplementary Planning Guidance instead by many District Councils with differing levels of commitment to the Guide and its philosophy.

The Guide has been influential and useful, but, though many of its recommendations remain relevant, was due for updating as a result of changing circumstances. The new version has been prepared by a working party of the Essex Planning Officers’ Association, representing all planning authorities in Essex, and aims to encourage the best practice in the design and layout of residential development.

The 1973 Design Guide was a response to concern about the poor appearance of new housing areas at the time. It set out underlying visual principles of past and present built environments and objective visual criteria against which proposals could be assessed. Whilst the 1973 Guide has had a measure of success in improving the quality of development, many of the problems originally identified are still present, and at the same time the process of applying the principles of the Guide has highlighted other problems present even in many of the better schemes which incorporate some of these principles.

The 1973 Guide described recent housing of the time as characterless and utopian, with prairie planning, anywhere type houses and cramped, overlooked back gardens. Unfortunately there is evidence of a return of these characteristics in recent cases where the principles of the Guide have been abandoned.

Even in those cases where there have been attempts to apply them, it is evident that many housebuilders have been pulling in the opposite direction. Thinking is still dominated by the perceived need to purvey the suburban ideal of the detached house on its plot. The problem is that when back gardens and side ways have been squeezed to get as many houses on the site as possible, and multiple car ownership catered for, often in front of houses, this ideal becomes unworkable. In such cases it has been possible to achieve no more than a compromise. Housebuilders often argue that their approach is dictated by the market, and yet, in those cases where there has been a more thoroughgoing acceptance of the principles of the Guide, the more attractive results have engendered a ready response from house purchasers.
A problem which the 1973 Guide did not address was the structuring of development. Both Design Guide and non-Design Guide housing frequently has the fault of an over-reliance on cul-de-sac layouts, with the result of disorientation for the visitor, indirect routes and lack of route choice for the pedestrian. Cul-de-sac layouts also increase traffic loads on feeder roads and therefore disadvantage residents of those roads.

Some architects have a preference for repetition of similar building forms and spaces, which is also disorientating.

There seems to be a feeling amongst many of those responsible for producing the built environment that housing areas should be no more than utilitarian, and that it is out of place to create a specific character for a residential area. The result of this tendency is that residents regard the area as merely a temporary place of residence until they can move to somewhere more attractive. The contention of this Guide is that an attractive place to live will also be an attractive place to visit, and that those historic towns and villages that are sought out by the tourist often make the most successful living environments.

Since the publication of the 1973 Design Guide there have been a number of changes in the context for setting physical criteria. Internal space standards became non-mandatory in 1975, and experience has shown rear privacy requirements not to have to be as stringent as recommended by the Guide.

On the other hand, the introduction of the minimum garden area has been found to be very workable, though the needs of small one and two bedroom houses were not envisaged at the time. A new concern has been environmental sustainability and design for energy efficiency in terms of passive solar gain.

Thinking on residential roads and access has continued to evolve. The Government’s Design Bulletin 32, resulted in a new set of standards as an addendum to the Guide in 1980. The 1990 revision of DB32 presented the opportunity of a further refinement of the standards in this version of the Guide. Increasing confidence in the ability of road design to reduce vehicle speeds and improve safety has resulted in greater flexibility in the ways in which roads can be laid out so as to enhance rather than detract from visual character and create coherence rather than fragmentation. Pedestrian movement is seen as better catered for by short strategic links between elements of the road system rather than by long segregated spine footpaths.
The Planning Context

The County Structure Plan identifies broad areas for growth and development in Essex within the context of which Local Plans specify which sites and locations are appropriate for different types of development. Both Structure and Local Plans require all new development to be well designed and to fit in with its surroundings. It is the purpose of this document to provide Supplementary Planning Guidance as to how to achieve these aims, and it should be read in conjunction with other design advice contained in Local Plans and design briefs.

The government also issues advice in the form of Planning Policy Guidance Notes, Traffic Advisory Leaflets, Design Bulletins, etc. Generally, planning authorities are expected to ensure that development is environmentally sustainable, efficient and well located in its use of land, does not give rise to unnecessary use of motor vehicles, is energy-efficient, is safe to move about in, provides minimum opportunity for crime, does not disadvantage the disabled and, significantly, is well designed in terms of its appearance.

PPG1 recognises that the appearance of a development is a material planning consideration and draws particular attention to the setting of buildings and the treatment of spaces between and around them. Case law* has established that the design of individual buildings is also a consideration insofar as it affects the layout, and this Guide therefore extends to the detailed design of dwellings.

PPG13 recommends that, where possible, residential development should not be single-use but incorporate commercial and employment uses in order to create more self-contained communities and reduce the need to travel. Whilst the actual creation of communities is beyond the scope of planning, it is an aim of this Guide to encourage layouts that foster the eventual emergence of a local community.

Application of the Design Guide

PPG1 states that good design should be the aim of all involved in the development process, and that it is primarily the responsibility of designers and their clients, who should recognise the benefits of engaging skilled advisers. Unfortunately the majority of planning applications for residential development in Essex continue to be submitted without the assistance of an architect. The overriding application of cost constraints by developers means that the planning system therefore has to remain the long stop for ensuring an acceptable standard of design.

It is hoped that the Guide will encourage more developers to re-examine their approach and employ an architect in order to meet this standard.

* Tarmac Homes (Essex) Ltd v Secretary of State for the Environment and Epping Forest District Council, 1990
At the same time, were good design to be dismissed as a matter of opinion or taste, planning authorities would be left open to accepting the lowest common denominator of quality. By setting out a clearly related structure of design and layout principles, planning authorities have a basis for refusing ‘obviously poor’ schemes, as required by PPG1.

As Supplementary Planning Guidance, this Guide is part of planning policy, and it is therefore not the intention that its provisions be set aside in exchange for other planning obligations, e.g. the provision of social housing by a developer, that may be negotiated by a planning authority.

**Context:**

Some sites will be ‘greenfield’ in which the context of surrounding development is not significant. Others will have to fit into a context of pre-existing development. Depending on the context, the planning authority will have to determine whether a new scheme should perpetuate the format of the surrounding area or establish a new one. If surrounding development has a strong pattern and character that could be detracted from by insensitive new development, the new scheme should pick up the theme of the existing and seek to enhance it. This would be the case, for example, with a site surrounded by pre-20th century development.

Obviously a context consisting of average twentieth century housing will not fall into this category. If, more typically, the surrounding area has no distinctive character and only a weak identity, the preferable course may be to establish a strong, new pattern, based on the principles in this Guide, that contrasts with the surrounding area and forms a focus for it.

In the case of, say, a nineteenth century context, the planning authority would have to be selective in its choice of policies from this Guide if it wished new development to fit in with its context.

**Essex Character**

It is the aim of this Guide to encourage new development to respect and fit in with the character of traditional Essex towns and villages. Obviously this character is very varied, but for the purposes of new housing it is the ‘background’ urban texture of a historic settlement which is important.

**(a) Pre-18th century pattern**

A surprisingly large proportion of the core areas of historic settlements is made up of structures and layouts dating from before the 18th century.

Generally buildings are joined together and directly front the street without front gardens. Building elements are shallow in plan - no more than 5 metres - and roofed at 50 degree pitch, with the skyline enlivened by chimneys and dormers. More usually the flank of the building is presented to the street, but gables and jetties project at intervals. Buildings of this date are timber framed and normally rendered in smooth lime plaster and roofed in hand-made plain clay tiles. White painted weatherboarding is sometimes found, particularly in coastal areas, and black-painted weatherboarding and clay pantiles on outbuildings and barns.

**(b) 18th and 19th century pattern**

18th and 19th century buildings are generally deeper in plan, typically two rooms deep, and have shallower pitched roofs, down to 30 degrees. In the 18th century these buildings tend to appear as incidents within the historic townscape. They are typically of orange-red brick with tiled or slate roofs and vertically-proportioned sliding sash windows. In addition, many older buildings were refronted in this style at the same period, but their origins are betrayed by their shallower plan and original roofs.
In the 19th century buildings also appear as incidents in the historic townscape, but whole streets of usually terrace but sometimes semi-detached houses start to be developed. Sometimes houses are built up to the street frontage and sometimes they have enclosed front gardens. They have vertically proportioned sash windows and substantial, centrally placed chimney stacks. In addition to red brick and tiled roofs, slate roofs are very common, and gault and Suffolk white bricks are found in the north of the county, with yellow London stock bricks in the south.

(c) 20th century

Whilst the 19th century disciplines survive up to 1914, the rest of the 20th century is characterised by a fragmentation of built form much of which has largely failed to relate to the townscape of previous centuries. Houses tend to be detached or semi-detached, sit on individual plots and are set back from the road. This type of development is referred to as suburban, and is typical of that found in all parts of the country. The format of such housing can be handled successfully in design terms, however, but only at densities below 20 houses per hectare (8 dwellings per acre) - see page 17 - in order to provide an adequate landscape setting. At higher densities the aim should be to create urban streets typical of pre-20th century development.

The Principles of Spatial Organisation

The aim of fitting in with the character of traditional towns and villages requires, for its fulfilment, the enclosure of space, whether by buildings or by landscape. Enclosed spaces are visually pleasing and create a sense of place. They provide variety of visual interest, and are more "comfortable" at the pedestrian scale. If the space is too large, a frequent problem, there is a loss of comfortable contact with the surroundings and a tendency towards a feeling of agoraphobia. The counterpart, less frequently encountered, is a space which is too small, leading towards a feeling of claustrophobia. Enclosed spaces also create safer and more secure environments, and influence drivers' perception of speed in residential areas.

Traditionally there are two ways of organising space and buildings:

a Rural System

Here the landscape contains the buildings. Buildings are set in landscape space: a mansion in its park or a group of farm buildings in their agricultural setting.

The key is: Landscape Containing Buildings.

b Urban System

Here the previous example is reversed, with buildings containing the space: the streets, squares, alleys and courts which make up the character of our historic towns and villages.

The key is: Buildings Containing the Space.

c Unsatisfactory Suburbia

Much twentieth century housing development has failed to recognise these two basic principles. This has resulted in unsatisfactory suburbia, where there are too many buildings for the landscape to dominate and yet buildings are too loosely grouped or of insufficient height to enclose space. THIS IS THE FIRST AND MOST IMPORTANT REASON FOR THE VISUAL FAILURE OF MUCH HOUSING DEVELOPMENT.
The increase in visual density from uninhabited landscape to the urbanity of the city may be viewed as a spectrum with individual buildings in the landscape forming one extremity and the city centre the other, and all other types of settlement pattern coming in between.

At the beginning of the spectrum is the truly rural situation, where an isolated dwelling or small group is located in the landscape. As such development is a very small proportion of the total of new building, detailed consideration falls outside the scope of this document. Suffice it to say that on such occasions siting and relationship to landscape should receive the same sort of care as would a proposal in a Conservation Area.

Next come those types of development where there is a greater quantity of housing laid out according to landscape-dominated principles, creating the illusion of a rural environment in a residential area. This is Arcadia, and its principles are set out on page 17. This effect cannot usually be achieved at densities over 8 houses per hectare (3 houses per acre). Then come those types of development in which trees still predominate and enclose the public space, but a more formal arrangement of the houses permits higher density, 10 to 20 houses per hectare (4 to 8 houses per acre). This is Boulevard Planning, and its principles are set out on pages 17 and 18.

In the middle of the spectrum is Unsatisfactory Suburbia, where houses are still set on plots, but in such a cramped fashion that there is no illusion of the houses being within a landscape setting yet the houses are too loosely grouped to contain spaces satisfactorily. Frontages are fragmented by gaps, and the public space dominated by estate roads and car hardstandings. This failure to organise space properly is the most fundamental reason why most suburbia fails visually.

At the farther end of the spectrum are urban groupings in which space is enclosed by more or less continuous building frontages. The principles of handling this kind of development are set out on page 21 on Development at Densities above 20 houses per hectare (8 houses per acre). These are the types of grouping characteristic of historic towns and villages in Essex. The extreme end of the spectrum, the City Scale, is not found in Essex, and therefore falls outside the scope of this document.

In a large development, one would expect to see a variety of densities of development, from Arcadia to urban groupings.

**Site Appraisal**

The planning applicant should carry out an appraisal of the site before designing the scheme. IN THE CASE OF SITES LARGER THAN 1 HECTARE (2.5 ACRES) THIS SITE APPRAISAL MUST PRECEDE OR ACCOMPANY THE PLANNING APPLICATION.

The site appraisal should cover the following aspects, which should be plotted on a plan:-

- An analysis of visual and physical character of the site and the visual and physical relationship of the site to its townscape and landscape context.
Views into and out of the site, landmarks in the surrounding area.

- Existing movement pattern and desire lines across and around the site.
- Access points to the site.
- Existing and potential nodal points within or near the site.
- Existing buildings and structures on and adjacent to the site and whether they are to be retained.
- Wayleaves and easement strips that cannot be built on.
- Slopes, wind shelter, overshadowing.
- Trees, their spread, height and condition, hedges, boundary features and whether they are to be retained.
- Wildlife habitats and whether they are to be preserved.

Decisions should be made as to where built frontages are required and to what scale in terms of building heights. For example, an existing road frontage may need continuation, or a space which is already partly enclosed may need completion of the enclosure by the new development. Attention should also be paid to ensure that the new development is a good neighbour to existing properties, for example that the sides and rears of existing properties do not become a frontage to a new road or publicly accessible area.

Existing key views and landmark buildings should be identified and respected by the new scheme. Similarly, points where new key buildings and views are required should be established, and the desirable form they should take.

IF THE SIZE OF THE DEVELOPMENT IS ABOVE 1 HECTARE (2.5 ACRES) TURN TO PAGE 9.
IF BELOW THIS SIZE, TURN TO PAGE 15.
Sustainability

Environmental sustainability is a range of concerns to do with ensuring that new development does not impose unacceptable burdens on local eco-systems and is designed in such a way as to promote environmentally friendly patterns of activity.\textsuperscript{1}

This means reducing as far as possible the need to travel.

As far as the planning authorities are concerned, sustainability requirements will need to be addressed in the following respects:

1. The development should be located in proximity to a town centre or similar set of facilities, and to public transport access. The suitability of location is a Local Plan function.
2. The development has a mix of residential and employment uses, tenures and dwelling sizes in order to reduce the need to travel. The Urban Villages concept is commended to developers in this connection.\textsuperscript{2} See paragraph on Proximity below.
3. The development is laid out in such a way as to maximise proximity to facilities and public transport and to encourage walking and cycling instead of the use of cars. See paragraph on Proximity below.
4. The development is laid out in such a way as to safeguard the existing ecology, improve the natural habitat and minimise heat loss from buildings. See paragraph on Landscape Structure below.

Mixed Uses

It is desirable that most larger developments incorporate a range of non-residential uses, both facilities for residents, such as shops, schools and community facilities, and also employment uses, such as offices and residential-compatible light industry. The location of these within predominantly residential areas will reduce the need for travel to work and facilities. No development of more than 500 dwellings should be without such employment uses integrally located within the development rather than in a peripheral business park, and it may well be desirable to include mixed uses in smaller residential developments as well. Developers should refer to the Local Plan in this respect.

Similarly, a mix of tenures and dwelling sizes maximises choice of location for residents and thereby reduces the need to travel.

A mix of uses in close proximity may justify a reduction in car parking requirements in the locality.

Proximity

The location of dwellings, facilities and public transport in close proximity encourages walking and cycling instead of car use for local trips.

Facilities, shops, employment, schools, etc should be clustered together on routes, pedestrian or vehicular, which lead directly into the cluster from surrounding, predominantly residential areas.

Residential accommodation should be mixed in with these other uses. Such clusters, neighbourhood centres or core areas, should be on a bus route, and no part of a residential area should be farther than 600 metres from such a cluster.

Preferably no part of a residential area should be farther than:-

- 400 metres from a regular bus route,
- 600 metres from a primary school,
- 1,500 metres from a secondary school.

Within 300 metres of a regular bus route, neighbourhood centre, cluster of facilities or town centre residential densities should be higher so as to place a greater proportion of residents within closer walking distance of facilities.

Landscape Structure

A larger development should be designed around a landscape structure. This should take as its starting point any existing land forms, water, vegetation and built features, which would act as

form-givers for the development with the purpose of assisting in achieving uniqueness of character. Existing ecology and natural habitats must also be taken into account and safeguarded as far as possible.

The landscape structure should encompass the public open space system (see page 15) but should also provide visual contrast to the built environment and constitute a legible network based, where appropriate, on existing trees and hedgerows. A block of trees visible above rooftops, for example, helps the legibility of a development from outside.

The landscape structure should, in addition, create a network of wildlife corridors linking with public open spaces and nearby countryside. Where based on retention of hedgerows, these should be within the public realm (not just in back gardens). The links should be fairly continuous (ie short breaks are possible) and should contain mixed indigenous tree and other plant species (see Appendix C) and some long grass, which provides protection for wildlife and attracts some species of nesting birds. Attention should be given to the creation of interdependent plant communities.

Where there is an exposed edge to open countryside, the planting of tree shelter belts around the edge of developments, especially on the north-east side, can reduce heat loss from dwellings within 150 metres in cold weather. Indigenous woodland tree species should be used, together with a mixture of evergreen and deciduous underplanting.

Trees also have an important role to play in more urban spaces. See page 25.

The design of the surface water run-off system should be considered in conjunction with the landscape structure. Balancing ponds for storm-water should contain a permanent body of water, and can be a valuable ecological and landscape feature. Planned absorption of surface water into the ground can help the water table level, though this is unlikely to be feasible in clay areas.

Permeability and Legibility of the layout

A street layout that encourages walking and cycling is permeable, in that it is well connected and offers a choice of direct routes to all destinations. It is also legible, in that it is structured by a distribution of distinctive places and spaces so that it can be 'read' and is thus easy to find one's way around. The following paragraphs explain how this can be achieved.

The Street System

A residential area should be structured by a street system made up of urban spaces formed according to the principles set out on pages 21 to 26. The design of the street system should start from the need to establish a clear, legible, articulating structure for the area, not from the technical
demands of traffic. This layout may, in part, be suggested by the topography, natural desire lines and accesses to the site. The street system should be ‘plumbed’ for traffic circulation, pedestrian use or cycleways after its form has been established by urban design criteria.

**Permeability**

It should be possible for pedestrians and cyclists to move freely between all parts of a layout, both locally and on a wider scale. The disadvantage of a layout based entirely on culs-de-sac and loops is that routes for pedestrians are indirect and boring and therefore pedestrian movement is discouraged. This creates dead areas which are vulnerable to property-related crime. Furthermore, cul-de-sac layouts result in higher traffic levels on feeder roads, with a consequent loss of amenity to residents of those roads.

A more permeable layout offers the pedestrian a choice of routes, which offers greater visual interest and therefore generates a higher level of pedestrian activity, and thus security. If there are more pedestrians around in the street there is a greater chance of casual social encounters and less chance of thieves being able to gain access unobserved to houses or cars. In order to allow free movement the ideal would be a deformed grid based on the small residential block. The advantages of culs-de-sac and loops in preserving amenity and quiet and supervised space can be combined with those of a permeable layout for pedestrians by bringing heads of culs-de-sac together, by creating pedestrian/cycle streets between parts of the road system, and by creating pedestrian/cycle links across major roads that would otherwise form a barrier.

There should be good connections between adjacent housing schemes, and wherever possible a choice of route between one location and another. Where it is not possible for traffic routes to link old and new residential areas, either because of ‘ransom strips’ having been left by developers, or else because of the undesirability of introducing new traffic into existing residential areas, there is often no reason why pedestrian and cycle links cannot be made between one area and another.

The aim of permeability is not, however, one that should be pursued to the exclusion of the need expressed below to focus the layout on cores and nodal points.

**Legibility**

**The Core**

The street network should focus on a core area of greatest pedestrian concentration. Large developments may need to provide this core on site. Smaller developments may focus on an existing core on a neighbouring site.
It is here that any non-residential uses should be located, e.g. primary school, community hall, local shops, pub and bus stop, and residential densities should be higher in this vicinity. The core area should be characterised by a high concentration of entrances to buildings opening directly off the street. Buildings should not be located in an isolated fashion, separated by car parks or access roads, and residential and non-residential land-uses should merge into one another.

The street system should radiate from the core area, with radial routes being more direct, and minor linking routes being more tortuous. These relationships of core to periphery have been found to generate greater levels of pedestrian activity.

Conventional neighbourhood centre

Pedestrian access across major road and car park

Residential area segregated from community facilities

Buildings directly front streets. High concentration of entrances

A neighbourhood core area

Car parks fragmented and located at rear

Residential buildings form continuous frontage with community facilities

Nodal Points

In addition to cores where non-residential elements can be introduced, it is desirable to structure a residential area around a series of nodal points. These may be irregular or regular shaped urban spaces formed at junctions of routes, and may be emphasised by key buildings or groups of buildings. Residential densities may be higher in the vicinity of such nodal points, forming a ‘village’ cluster, with lower density areas between one cluster and the next. Provided there is sufficient concentration of non-residential uses and community facilities in the main core area, it may be appropriate to locate some other community facilities, e.g. convenience shop, child care nursery or pub, at nodal points to act as a focus and generate pedestrian movement.

Character Areas

A large residential area should have a variation in character between different parts. This variation should not be based on development density or artificial creation of social differences, but on different types of space, building forms and materials. Whilst it is an aim to build in identity and sense of place into all parts of a development, the creation of a particular identity in different parts of the development will do much to define the special character of each area.

Edges

Edges may be the outside urban edge to countryside, an edge against a major road, an edge against an open space, or a line of transition between an area of one character and that of a different character.
According to their importance, edges should be treated in different ways. Public open spaces should be treated as focuses on to which houses front, rather than tucked away behind the backs of houses.

In order to avoid domination by back fences, major roads and countryside edges should also be fronted by houses, even where it is not possible to take vehicular access direct from the major road, and access has instead to be taken from service roads or private drives running parallel to the road, or else from behind.

**Urban Grain**

In those cases in which it is decided to perpetuate the pattern of the surrounding area, attention should be paid to repeating the urban grain determined by the pattern of plot subdivision and building form. For example, where terraces of houses are the norm, the new development should also consist largely of terraces. Where houses are set forward up to the street line, the new development should do the same. Where the existing pattern is irregular, irregularity should also be characteristic of the new scheme. The designer should beware of laying out the new development to a pattern generated by the T-square on his drawing board or by the internal logic of the site, which does not relate to the surrounding urban grain and which may result in a ragged, unconsidered edge to existing development. Care should be taken to resolve any "mismatch" of orientation within the site, to the benefit both of the relationship with adjoining areas and of the consequently enhanced interest of the spaces within the site.

**Landmarks**

Landmarks are distinctive buildings, spaces, sculptures, etc that should be placed at points in the network where they can aid orientation. They can be particularly useful in areas away from nodal points or other distinctive places.
They may also fulfil a useful function in aiding orientation in the view from a major road. A landmark could be not only a distinctive building, but a taller one, designed to be seen over a wider area.

**External Image**

As seen from the surrounding landscape, the development should have a clear and well-defined image. This is achieved by

(a) a clear design treatment of the urban edge (see Page 13 above),

(b) clear and defined entrances to the development (eg pinch points),

(c) skyline and roofscape, which is made up of

i a texture of roof forms generated by the forms of individual houses,

and

ii the location and roof treatment of key buildings within the development, which will aid orientation. Taller buildings and blocks of trees also serve to structure the external view.
Protection against Noise Sources

The best way to limit the effects of external noise is to locate new housing away from major noise sources, e.g. heavily trafficked main roads, airports or heavy industry. PPG24 'Planning and Noise' recommends that sites subject to noise levels above 72 dB LAeq,T between the hours of 07.00 and 23.00 and 66 dB LAeq,T between the hours of 23.00 and 07.00, should not be used for new housing. Sites subject to between 55 and 72 dB LAeq,T 07.00-23.00 and between 45 and 66 dB LAeq,T 23.00 - 07.00 may only be developed if suitably protected from the noise source. Barrier blocks of single-aspect housing are a way of protecting these sites, as are earth mounds.

Public Open Space

All open space in a development should be obviously useful and visually pleasant. Thus all public areas, whether squares, streets, pedestrian links or parking courts are part of the provision of different types of space, each with their own function and all designed to provide a high level of amenity. The provision of arbitrary pieces of 'public open space' can result in spaces that are divorced from the main pattern of public street spaces, are neither useful nor attractive, and indeed are a nuisance to residents. They are also expensive to maintain.

Experience shows that the most effective public open spaces are large, multi-purpose informally supervised parks. These are best allocated by the Local Plan process or in a Design Brief and those planning authorities that operate a percentage open space policy should aggregate the requirements of a number of smaller developments to create these larger, more useful open spaces. This is becoming even more necessary as Parks and Leisure Departments feel the effects of financial stringency and are less willing to adopt smaller and more uneconomic open spaces. In some cases management companies may have to be set up to run and maintain open spaces of whatever size.

Whilst parks should be the key open space provision, there is a role for additional smaller, more localised open spaces in order to create a more varied townscape. On page 34 it is suggested that houses should have reduced private garden areas provided they face, back on to or are adjacent to a substantial area of well landscaped and properly maintained communal open space. This is the situation analogous to the Georgian square, and in such cases it would be appropriate for the space to be maintained by a management company. This provision compensates for smaller gardens and should be additional to any percentage open space requirement by a planning authority.

Parks and school playing fields should preferably be fronted by houses rather than tucked away behind so that they become a more obvious part of
the circulation system, benefit from informal supervision from the houses and contribute to the amenity of outlook of the houses. They should be a focus for the pedestrian and cycle network, and it should not be necessary to cross a main road (Type 2 or above) in order to get to one.

**Children’s Play**

Whilst the safest place for small children to play is the back garden, it is recognised that, for many types of play activity, older children prefer to play in roads and parking courts. Provided the road system is designed for slow vehicular movement and gives priority to the pedestrian there is no reason why this cannot be accommodated, and the addition of objects such as railings and benches, with extra paved area as part of the street space, can facilitate play and help populate the street, which has the benefit of reducing the opportunity for crime.

Where there are a number of family dwellings with less than 100 sq m gardens, DOE Circular 79/72 recommended provision of play space on the basis of 3 sq m per child bedspace which, at urban densities of 10-15 dwellings per acre (25-37 dwellings per hectare) would result in 3-4 per cent of the site being given over to children’s playspace.
The aim, as of criteria for layout at higher densities, is the creation of a pedestrian scaled environment by means of enclosing space and structuring chains of spaces. The difference is that the space is enclosed by trees, hedges and shrubs rather than buildings, which become free-standing rather than space-enclosing elements and are contained within the landscape; this is the legitimate context for the detached house.

Arcadia

**Densities up to 8 houses per hectare (3 houses per acre)**

Arcadia is the creation of the illusion of a rural environment by using the picturesque approach to landscape design as typified by the layout of parks of great country houses in the eighteenth century. The principle was the use of meandering walks which successively revealed surprise features hidden in a dominant landscape.

In the same way, early 'leafy' suburbs of the nineteenth and early twentieth century conceal houses among mature trees so that the visitor is more aware of the landscape setting than of the houses.

Today's Arcadia should strive for the same effect, with a layout devised to allow houses to appear at intervals among trees as surprise features in the landscape. This effect cannot be achieved at densities over 8 houses per hectare (3 houses per acre).

Land economics may well dictate that housing at this density is at present the exception rather than the rule in new residential areas. If a planning authority wishes to see a wider use made of development laid out according to Arcadian principles, it would do well to consider a special notation for such sites in its Local Plan in order to predetermine an appropriate land value.

As Arcadia is dependent for its effect on a dominant landscape, the most suitable sites will be those which already have a significant density of mature trees and hedges. Consideration must also be given to how the existing tree cover can be enhanced by new planting or, where existing vegetation is sparse, a new pattern of substantial tree and hedge cover can rapidly be established. The need for rapid establishment should not, however, influence a choice of plant material that is alien to naturally occurring species in Essex (see Appendix C).

Front gardens should be enclosed by hedges in order for the landscape to dominate the houses. Clearly, open plan front lawns that show off cars parked on drives, built enclosures such as walls with railings, substantial gates, etc. are not appropriate to this concept.

Boulevard Planning

**Densities up to 13 houses per hectare (5 houses per acre)**

Boulevard Planning employs the rural principle of spatial organisation, in that the landscape dominates the buildings. However, it also uses some of the urban principles of design, in that trees are used to enclose spaces in a manner similar to the way buildings are used in the urban situation.

There are two possible variations:

1. Large trees grow on the front boundary of gardens (this would have to be a requirement of the planning consent with the established trees protected by Tree Preservation Orders). Houses appear at intervals seen through drive entrances, but no more than one or two are apparent at any viewpoint. Trees always
provide the link between one house and the next, with more planting at the rear to unify the composition and contain the space between the houses. Care must be taken to ensure that there is sufficient space for trees to establish and mature. The road is a shared visual space for motorists and pedestrians.

The length and variety of linear spaces needed to avoid monotony is broadly governed by the principles explained on page 23.

Such layouts work particularly well when the streets form straight avenues or meander in a gentle, serpentine manner.

**Boulevard Planning**

*Densities up to 20 houses per hectare (8 houses per acre).*

A further variation is possible with a layout relying on a subtle combination of landscape and buildings. Part of the composition will rely on creating and enclosing spaces by trees and hedges, and part will be reliant on building groups. The right relationship must be created between the height of buildings and trees and the width of the spaces between them, following the principles on page 21.

Whilst the use of detached houses is possible in this context, the effect depends on the use of a common architectural style and detailing for all the houses, on locating garages to the rear, and on using gateways, arches, railings, etc to link the houses into one composition. Similarly the houses must be positioned in a strict geometric pattern. It is this geometry of crescent, circus, oval or rectangle that will provide the necessary order. The success of such layouts is dependent on abundant and appropriate tree planting. Sparing use should be
made of areas of housing laid out in this way, with layouts at over 20 houses per hectare (8 houses/acre) predominating. On a small site it would not be appropriate to use this format at all.

Tree and Hedge Species

As a general rule deciduous species should be chosen, as they provide visual interest throughout the year, allowing light and air to penetrate to ground level during winter. Evergreens, however, can be used to conceal unsightly features, or to act as a focal point. For further details see Appendix C.

The Design of Buildings within the Landscape Context

Whilst the design of buildings in, say, the Arcadian context is not as constrained as within the urban context, nevertheless building forms should follow the regional tradition (see page 37), should avoid the deep plan (see page 38) and should follow the recommendations on elevational and detailed design (pages 41-49).
As already explained, the prime underlying principle of all urban places should be the creation of a pedestrian scaled environment by means of enclosing space by buildings. If space is not satisfactorily enclosed, an attractive urban place cannot be achieved. Similarly chains of spaces must be structured in such a way as to add up to a meaningful urban place.

**Pedestrian Scale**

In order to encourage walking, and to create spaces in which people feel comfortable, any publicly accessible spaces must be visually satisfactory to the pedestrian.

This means that spaces must be visually comfortable in terms of their height to width ratio (see below), balance of static and dynamic spaces (page 22) and their visual length (page 23).

Pedestrian movement is sufficiently slow to allow scrutiny of one's surroundings and to examine and decode a wealth of visual information, much of it at an unconscious level. Without an abundance of visual stimuli the pedestrian experiences boredom and alienation.

There must be sufficient visual interest within the planes of the enclosing buildings to engage the eye. Repetition of similar building forms should be avoided, except where formal spaces are being created and there is compensatory detailed design enrichment. At the same time there should be sufficient density of interest in changes of frontage width and building line, surface texture of facing materials, window and door types, features such as gables, projecting wings, bays, etc. and a varied skyline with chimneys and dormers, to encourage the pedestrian to explore. There is a spectrum between a chaotic proliferation of detail at one end and severe simplicity at the other. Between these extremes an acceptable balance must be struck. Visual variety will be enhanced where there is also variety of building types and uses, ie not purely residential.

**Height of Buildings and Width of Spaces**

In order to create satisfactory enclosure of space related to the human scale it is necessary to establish a suitable ratio between the width of the space and its enclosing buildings. An ideal relationship for pedestrian-dominated dynamic spaces is for the width of the space to be equal to or less than the height of the enclosing planes.
In practice this can be difficult to achieve, and gaps in the height of enclosing buildings, partial widenings of the space, etc should be compensated for by narrowing the rest of the space and/or increasing the building height of one side. The secret of success is that the building must be of sufficient height to command that part of the space. In certain circumstances roof slopes, gables, dormers, chimneys and other skyline features can increase the apparent height of buildings and thus their ability to enclose space.

**Dynamic Spaces**

Most urban spaces will inevitably be linear and corridor-like, contained by buildings and other features. If the pedestrian alone were to be accommodated, such spaces need be no wider than 2 metres, but the requirements of building outlook and the manoeuvre of vehicles normally preclude such intimate spaces. Generally, the narrower, the longer and the taller the enclosing buildings of such a space, the more it imparts a feeling of dynamic movement.

**Static Spaces**

Whilst the overall network of routes will have a general linear tendency, the skilful introduction of more placid areas will have a welcome effect. These are spaces that encourage the pedestrian to stop and linger. Such static spaces can take a variety of plan forms. Circular spaces and squares bounded by a plane of continuous height are the strongest types. Clearly the impact of the static character can be enhanced or diminished by its architectural treatment. It can be further reinforced by the addition of a central feature (see also page 63).
Static spaces should be sufficiently strongly enclosed that a linear feature such as a road passing through does not detract from the feeling of enclosure. Such an effect may be mitigated by a design treatment of the ground plane that emphasises the static nature of the space, but this is no substitute for effective enclosure by buildings.

**The Problem of Over-wide Spaces**

The space accommodating a vehicular road will inevitably be wider than the ideal situation described on page 22. The pedestrian will perceive such spaces as over-wide. A static space of this width, such as a market square, would, however, not appear over-wide due to its limited length. This effect can also be created by the design of buildings which command and, at least partially, enclose the space.

Another solution is to treat each street frontage as a more or less unbroken wall or edge, with the footway hugging the built frontage to give a sense of shelter. A further solution is to subdivide the width of the street by rows of trees to create three parallel spaces, i.e., two footways and the carriage-way. In such cases there could be greater fragmentation of the frontage, as this would be concealed by the trees.

**Length of Spaces**

An over-long linear space can be daunting or monotonous to the pedestrian as too much is revealed at once. This problem may be overcome by limiting its visual length by complete or partial closure formed by a taller terminal building, a curve in the street, a change in the building line, a pinch point or a change in level. These devices conceal the way ahead and arouse the curiosity of the pedestrian. They also reduce the dynamism of the space.

It is necessary to achieve a variety of spatial experiences along a route. This may be done by breaking the linear space into a series of linked sub-spaces more related to the human scale.
These sub-spaces can be created or hinted at by relatively minor variations in the height-width relationship, breaks in the frontage line, angling facades, and the detailed design of the buildings. They may be more positively formed by pinch points, bridging over the space, or by wide eaves overhangs and projecting high level features.

**Continuity of Route**

The continuity of a pedestrian route needs to be emphasised by minimising breaks in the built frontage. Gaps for road junctions, etc need to be sited so as to have as little impact as possible on the visual continuity. The route should be a unifying element, tying groups of buildings together and making its whole length a composition in itself. However, such a route will need a variety of spaces along it in order to provide a diversity of spatial experience.

**Character of the space**

A balance should be created between diversity and unity in the overall design treatment. A totally unified scheme would be one in which spaces, building forms, roof pitches, eaves lines, openings and materials were the same throughout the scheme. A totally diverse scheme would be one in which they were all different. The former would be monotonous, whilst the latter would be chaotic. Clearly there is a band of acceptability between these extremes in which a balance must be struck with some elements varying and others consistent, and in this lies the secret of the attractiveness of places. This can be seen in many historic settlements; in some, for example, spaces, forms, roof pitches and eaves vary, whilst a pleasing unity is imparted by consistency of materials and elevational openings. Other settlements owe their character to a variety of materials but with consistency of street frontage and plot width.

Another facet of the split between diversity and unity is that between formality and informality. Within the band of acceptability, formal design may be characterised as that in which there are a greater number of consistent elements, tending towards unity, whilst informal design is that in which there is a greater variety in elements, tending towards diversity. Formal design tends to suppress the individuality of the dwelling in the interests of creating an overall composition of greater coherence than would be possible dealing purely with individually expressed units.

Spaces may be treated in either a formal or an informal way. A formal space is unified and symmetrical in its treatment, and is based on one or more axes. The character of the space may be reinforced or contrasted by the design of the buildings. An informal space is more diverse and complex in its treatment, the balance between diversity and unity being struck in a more subtle
The contrast between formal and informal spaces is stimulating, and prevents the monotony of a completely formal or a completely informal layout. Normally formal spaces should be placed within the matrix of an informal layout so that they can act as a focus. The repetition of similar spaces should be avoided, as this results in monotony and disorientation.

**Use of Landscape in Urban Spaces**

Trees and hedges can be used as part of built frontages, or used in their own right to articulate spaces, in the form of a barrier or screen.

For example a block of trees in the centre of a square may transform the square into a linear circuit of spaces, or a block of trees across the middle of a large or long space may transform it into two separate spaces.

A tree may be used as a centre point to punctuate and reinforce the character of a space or rows of trees may give directional emphasis to a dynamic space. It is important that the design of the space is such that it can accommodate the mature growth of trees suitable for these purposes.

The proportion of tree enclosure to built enclosure will affect the identity of a space, giving it a 'hard' or 'soft' character. Similarly, an area with a higher tree content will have a different character from one with a lower tree content. See Appendix C for suitable tree species for urban spaces.

**Treatment of Ground Surface**

The ground surface is one of the enclosing planes of any space. It can therefore be treated in such a way as either to complement or contrast with the character of the space and its enclosing planes. It may have a greater or lesser proportion of hard paving to soft planting, and it may be designed in a more formal or less formal manner.
For example a wider space may appropriately have a higher proportion of soft or planted surface area, as otherwise the space would be dominated by the monotony of a large expanse of paving. A tighter, more enclosed space, on the other hand may appropriately be hard or paved. A continuity of materials between paving and the elevations of buildings will give a strongly unified effect to a space.

Unexplained changes in material should be avoided, but changes can be used to delineate accesses, carriageways and the boundaries between public and private areas.
**Continuity of Frontage**

In order to enclose spaces and create continuous pedestrian routes (see page 24), as much continuity of built frontage as possible should be achieved. The following means are available:

(a) Having a high proportion of dwellings joined to one another in terraces. This need not mean suppression of the individuality of the dwelling; historic towns and villages are largely made up of individual buildings which happen to be joined to one another. Terraces also have the advantage of economy of construction and improved insulation, and therefore energy efficiency. If it is desired to have a high proportion of detached houses these should be provided within a lower density context, see page 17.

(b) Even where space for the access of cars is required between buildings, it is possible to maintain continuity by bridging over at first floor.

(c) At the ends of terraces, or in the case of detached buildings, the illusion of continuity may be created by forming an overlapping right-angled corner which, when approached, cor

(d) The flank of the garden of an end house is the frequent cause of a break in frontage continuity. These should be located in non prominent positions in the layout, or else the house should be designed as a corner-turning building which screens at least part of the garden flank, with the remainder screened by a wall at least 1.8 m high. The length of garden walls on the street frontage should, however, be kept to a minimum.

It is a difficult task to enclose urban space with a range of house types the majority of which are detached or semi-detached, as the gaps tend to dominate and the space visually leaks away. The use of a large proportion of detached or semi-detached houses is therefore unconducive to enclosure of urban space and should be avoided in the urban context. The correct context for these is at densities below 20 dwellings per hectare (8 dwellings per acre).
Relationship of House to Road

In order to enclose space effectively, buildings will normally be sited at the back edge of the public footway.

This will require car parking to be sited between houses, beneath upper storey structures, or within garages to the rear. This has the advantage of reducing the visual impact of on-site parked cars. It also has the advantage of increasing the amount of site area available for private rear gardens.

The enclosure of urban space is made impossible where the fronts of houses are all set back from the road sufficiently to accommodate a visitor parking space in front. This may occur due to the use of integral garage house types, or because the houses are in a terrace without parking accommodated beneath or behind houses.

For this reason, only sparing use of integral garage house types should be made, or else visitor spaces should be located elsewhere than in front of garages. Garages may with advantage be freestanding so that they can be located anywhere on the plot. In the case of terraces, visitor parking should be located at the end of the terrace or behind, unless the terrace fronts an enclosed or partially enclosed parking court or square, see top right.

Attention should be given to the provision of covered, secure cycle storage in a position at least as convenient as the garage, possibly by widening the garage to accommodate cycles. One of the greatest deterrents to cycle use for local trips is the inconvenient location of cycle storage at home.

There is, exceptionally, a role for front gardens in layouts at densities over 20 dwellings per hectare (8 dwellings per acre). One or two dwellings in a street sequence may be set back to create an incidental feeling of extra space and greenery. Alternatively, three-storey houses are tall enough to maintain a feeling of enclosure even with front gardens, which, in such cases, should be large enough to contain a tree.
Where the layout requires that a house be set back from the road, the space in front should either be a publicly accessible paved area forming part of the general street space, or else an enclosed front garden with a wall, railing and/or hedge of at least waist height.

In all cases care should be taken that all spaces are perceived to be overlooked by windows, and that alcoves and corners where an intruder could hide are not created. Indeterminate open areas in front of houses should not be formed.

Experience shows that residents have a lower expectation of privacy from the public or access side of the dwelling, and it is therefore not necessary to be as stringent in requirements for privacy on this side. Traditionally, houses were often set forward up to the back edge of the footway in the street, but because of the narrowness of the windows and the fact that they were well inset, a wide field of vision into the interior was not offered.

Where houses were set back, a hedged or walled screen to the front garden inhibited the view in. Houses that are set back with "open plan" front gardens and wide windows offer less privacy from the street, particularly if there is a through living room where daylight from the rear silhouettes figures in the room.
It is therefore recommended that designers return to the traditional format of vertically proportioned windows and houses either set forward to the back edge of the footway, or, exceptionally, set back behind above eye level hedged or walled front gardens. This accords with good practice in the creation of townscape and the enclosure of space (see page 21).

**House Design within the Layout Context**

Rather than deploying a range of house types which all have the same relationship to the road, the developer should have at least a proportion of houses which perform a particular role according to their position in the layout. The plan forms of houses should, for example, be capable of turning both external and internal corners, there should be houses of sufficiently distinctive design to be capable of terminating a vista or changing the direction of a road, (see page 13) and there should be houses whose private garden side is at right-angles to their entrance side.

Other useful houses could be of tapered plan form, capable of use in curved terraces or crescents, and houses of three or more storeys for use where extra height is required. There may be situations where a combination of several of these attributes is needed.

Where houses front a curve in the road, there has been a tendency to stagger the houses in a saw-tooth fashion in order not to depart from the planning grid. This is T-square planning which results in a jagged space and enclosing roofline uncharacteristic of traditional streets, where instead house fronts curve to follow the road alignment. It is recommended that the latter practice is adopted in new development. The consequent slight irregularity of house plan is a small penalty to pay for the more harmonious street scene that results.

**Daylight and Sunlight**

Good natural light makes dwellings more attractive, pleasant and energy-efficient. Housing layouts should be designed to maximise daylight and sunlight to dwellings as far as possible, but not to the exclusion of other considerations, such as privacy or the achievement of an attractive streetscape.

(a) **Daylight from the sky**

The Building Research Establishment’s report "Site Layout Planning for Daylight and Sunlight" 1991 suggests that acceptable daylight in interiors is
achieved if a 25° vertical angle from a point 2 metres above the floor at the façade is not obstructed. Applied to the fronts of houses, this would result in at least a 10 metre spacing between opposite house fronts in a street.

However, in many cases it will be desirable for townscape reasons for the spacing to be less (see page 21). In houses one room deep, there is obviously the possibility of supplementing the amount of daylight from the rear. Raising window head heights and keeping rooms shallow in plan are other ways of increasing the amount of daylight when buildings are closely spaced. Application of the 45 degree rule (see page 40) to projections and extensions will minimise loss of daylight. In houses on the north side of such streets, ground floor habitable rooms should take daylight from both front and rear.

(b) Sunlight.

It is not a reasonable requirement for all dwellings to have sunlit rooms. Often a view on to a sunlit external space is preferable. However, a room will be sunlit if at least one main living room window faces within 90 degrees of due south and is not obstructed according to the criteria under (a) above.

(c) Passive Solar Gain.

Again it is not a reasonable requirement for all dwellings to benefit, but heating costs in winter can be reduced by orientation and design for solar heat gain. Any wall containing windows oriented within 30 degrees of south will benefit. This does not mean that all roads and houses have to run east-west, as rear wings can project even from a north-south aligned house to take advantage.

In such cases larger glazed areas, especially full height windows facing the sun, and the internal zoning of houses so that living rooms are on facades within 30 degrees of south are necessary. These windows should not be obstructed by buildings or evergreen trees above a 13 degree vertical angle from the mid height of the window. Also projections which cause permanent shade on north facades should be avoided.

Rear Privacy

Residents have a higher expectation of privacy from the private or garden side of the dwelling. In a low density layout it should be possible to avoid any overlooking, but at normal urban densities (above 20 houses per hectare or 8 per acre) some overlooking is inevitable.

(a) Remoteness.

With* rear-facing habitable rooms, the rear faces of opposite houses approximately parallel, and an intervening fence or other visual barrier which is above eye level from the potential vantage point, a minimum of 25 metres between the backs of houses may be acceptable. However some planning authorities require more than this, and applicants should consult their local planning authority on this and other rear spacing requirements.

* All the following provisions also apply to sides or flanks of houses containing windows of habitable rooms. For sides not containing windows of habitable rooms, see page 32 section (b) on privacy by design.
Where the backs of houses are at more than 30 degrees to one another this separation may be reduced to 15 metres from the nearest corner. These dimensions should also be applied when considering future extensions which have rear-facing windows. Again, applicants should check with their local planning authority whether they will accept this dimension. Where houses are at right angles to one another, see (b) below.

Where new development backs on to the rear of existing housing, existing residents are entitled to a greater degree of privacy to their rear garden boundary, and therefore where the rear faces of the new houses are approximately parallel to the existing, the rear of new houses may not encroach any closer than 15 metres to an existing rear boundary, even though with a closer encroachment 25 metres between the backs of houses would still be achieved. Where the new houses are at an angle of greater than 30° to the existing, proximity may increase proportionately down to 1 metre from the boundary. Where the new houses are at right angles to the existing, there are no windows in the flank end and no problems of overshadowing the new houses may encroach up to 1 metre from the boundary. Again, some planning authorities may require a wider spacing.

Upper storey flats can cause problems of overlooking from living rooms, and therefore any rear-facing upper storey living room should be no closer than 35 metres to the rear of any other dwelling. It should, however, be borne in mind that oblique views over side boundaries from upper storey living rooms can also be a problem, and this should be safeguarded against.

(b) Design.

The rears of houses may be positioned more closely together than as stipulated under (a) above if one or both of the houses concerned are designed in such a way as not to overlook one another. This would require an intervening above eye-level fence or other visual barrier between facing ground floor windows and no rear-facing, upper-storey bedroom or living room windows. This may be achieved by facing upper-storey windows in other directions, by having projecting rear wings that block the view, or by internally zoning the accommodation so that only bathrooms and landings are rear-facing, and provided with above eye-level windows.
An above eye-level secondary window to a bedroom is also possible on a privacy-sensitive elevation. In the case of a completely windowless elevation, the house could be positioned on the boundary, provided it did not cause unacceptable overshadowing of a neighbouring house or garden.

Private Sitting-Out Areas

All houses should have a private sitting out area not overlooked by adjacent or opposite living rooms or sitting out areas. This area should extend at least 3 metres and be screened from adjacent properties by walls or fences above eye level from a potential vantage point.

An acceptable degree of privacy would be as for rear-facing living room windows, i.e. either an intervening above eye-level fence or other barrier and a rear separation between the backs of houses of at least 25 metres, or the design of the opposite house so that windows face in other directions. (With the same proviso as for rear-facing living room windows, i.e. that where the houses are at more than 30 degrees to one another the separation may reduce to 15 metres from the nearest corner.)

Particular attention must be paid to the potential problem of overlooking from the living rooms of upper storey flats, which should be no closer than 35 metres to a private sitting-out area unless it is effectively screened from view.

Sitting-out areas should be located so that they receive sunshine during at least part of the day. On north-facing rear elevations, care must be taken to avoid rear projections that result in permanent shade. In some cases it may be preferable to locate the sitting-out area elsewhere in the garden than against the rear of the dwelling, and if so it must be subject to the same privacy requirements. Private sitting-out areas should also be incorporated as part of the garden requirement for flats (see below).

Garden Size

The 1973 Design Guide required a minimum private (i.e. rear) garden size of 100 sq m for most types of houses. This provision has been found to be an acceptable and workable minimum size that accommodates most household activities and is at the same time adequate to offer visual delight, receive some sunshine, and encourage plant growth. The BRE report "Site Layout Planning for Daylight and Sunlight" recommends that certainly no more than two fifths and preferably no more than a quarter of the garden should be prevented by buildings, walls or fences from receiving sunshine on 21 March.

The 100 sq m minimum garden size is easily achievable for three or more bedroom houses provided the houses are of wide frontage format, but narrow fronted houses may result in long, thin, impractical gardens. This is yet another reason for minimising the use of this type of house. Generally, designers should try to create as far as possible usable rectangular garden shapes. Some local authorities...
may have different minimum garden sizes, and applicants should consult the relevant District Council Planning Department.

There are circumstances under which the insistence on a minimum 100 sq m garden size is not appropriate. These are as follows:

(a) **Houses of one or two bedroom size.**

Such houses usually have such a small footprint that provision of a 100 sq m garden is not practicable without being excessively long and thin. In any case, since these are dwellings for smaller households the requirement by residents for garden area is less.

Different local planning authorities have varying garden size standards for one and two-bedroom houses. 50 sq m is the most common, but applicants should consult the relevant District Council Planning Department.

These houses must be indicated as being either extendable or unextendable. In the case of an extendable house, the initial planning application must show the shape of an eventual extension, and the garden area must be calculated excluding the ground that would be occupied by the eventual extension. Unextendable houses will have the householder’s right to extend under the General Permitted Development Order withdrawn. Permitted Development rights to extend will also be withdrawn where the garden is less than 50 sq m.

In the case of unextendable one-bedroom houses some local planning authorities may allow communal garden provision. In such cases this will be to the standard for flats, i.e. 25 sq m per dwelling minimum, and a planning condition will be imposed that the garden is to remain communal in perpetuity. This garden space is to be entirely on the private, non-entrance side of the house and to contain a screened, unoverlooked sitting-out area (see page 33) adjacent to each house.

(b) **Walled patios or private courtyards.**

In higher density situations it may be appropriate to reduce minimum garden sizes to 50 sq m, provided a private, sitting-out area for each house can be achieved, unoverlooked by any window either at ground or first floor. The loss of sunlight in such situations may be an acceptable price to pay for a tighter urban format or closer proximity to central facilities for example. Rights to extend will be withdrawn in these cases.

(c) **Houses facing, backing on to, or adjacent to a substantial area of well landscaped and properly maintained communal open space.**

This is the situation analogous to the Georgian square, in which residents have immediate access to the communal space for children’s play and sitting-out. In such cases the private garden could be reduced to 25
sq m, though different planning authorities will have varying policies. Again rights to extend will be withdrawn.

**d) Houses performing a particular role in the layout.**

Where the majority of houses comply either with the 100 sq m minimum garden size or one of the other standards above there may be some houses which, due to their situation in the layout, cannot be provided with a private garden to the required standard.

These may be, for example, houses which turn external corners or are required for townscape reasons in locations which are hemmed in at the rear. If the standard were strictly adhered to there would be gaps in these positions, and the whole street scene would be the poorer for their lack. In a development comprising a number of houses, purchasers will have the choice whether or not to buy one of these ‘special’ houses, and planning authorities should therefore be flexible as to how much private garden area they will require in such situations.

**e) Flats**

For two or more bedrooomed flats (which may be occupied by households with children) communal residents’ gardens must be provided on the basis of a minimum area of 25 sq m per flat. They must be screened by above-eye-level walls or hedges, and must contain a sitting-out-area that receives sunshine during at least part of the day. Unusable strips of space between car parks or roads and buildings will not be counted as part of the communal garden provision. Although similar provision is welcomed for one-bedroomed flats it is recognised that residents of such flats may be happy to forego this amenity if there is access to other local open space, and in order to have the benefits of living in a town centre or other core area. Applicants should check with their local planning authority the circumstances under which a garden for one-bedroomed flats may be foregone.

In addition balconies may provide outdoor amenity space in closer proximity to an upper storey dwelling. A balcony or terrace over 5 sq m in extent will count towards the total garden provision for the flats. In an urban situation such a balcony or terrace would be acceptable as the only outdoor amenity space for a flat. Care must be taken to limit overlooking of nearby private gardens and sitting out areas from balconies or terraces. It may be necessary to provide other space around the development additional to this minimum requirement in the case of flats located in a Boulevard planned area.

**Accessibility for Disabled People to Dwellings**

It is good practice to design for all new dwellings to be able to be visited unassisted by disabled people as far as the entry to the dwelling at least. The attention of developers is drawn to the recommendations of the Joseph Rowntree Foundation’s ‘Lifetime Homes’ concept, but it is accepted that it is unrealistic for all new houses to cater for occupation by mobility-impaired people.

As far as planning authorities are concerned, it is sufficient for there to be a flat area 900mm x 900mm minimum on the same level as the threshold outside the entrance to each dwelling. This flat area may be approached by steps or a ramp of maximum gradient 1 in 12 and minimum width 900mm with handrail where appropriate. The entrance door and any gates should be a minimum width of 800mm.

Frequently it is not practicable to accommodate this flat area and its approach outside the front door, for example if the front door opens straight off the footway and its threshold is above the footway level. In such cases it is acceptable for such access to be taken to an entrance at the side or through the back garden.
So far buildings have been regarded solely from the point of view of their role in enclosing and defining space, which is a matter of urban design. This section considers the form and design of individual buildings, which is a matter of architecture. As a major proportion of building carried out in Essex is not designed by anyone with formal architectural training, it is legitimate to set out the design requirements that the planning authority will have.

**Regional Building Forms**

The traditional buildings of Essex are normally made up of rectangular, (not square), plan forms, with pitched roofs spanning the narrower plan dimension. Such spans are rarely greater than 6.5 metres, but more usually of the order of 5 metres. In order to fit in with the urban landscape of Essex, new buildings should also employ these forms and dimensions.

Buildings of more complex form should be composed of an assemblage of such forms to make, for example, L plans, T plans or deeper plan forms made up of parallel ranges. In all cases, each element of the plan should have its own roof pitched over the shorter dimension. Such roofs should normally be pitched at about 50 degrees.

Each building should be composed of a 'family' of forms, ie with roofs of similar pitch and without discordant flat-topped elements.

In an assemblage of forms, there should be a principal element to which subsidiary elements are added. Complex plans should not be enclosed in an enveloping volume out of which pieces are cut to create subtractive form.

The use of deep plan (more than 5 metre) buildings roofed with a single span results in wide gable ends uncharacteristic of traditional buildings in Essex, and in problems of roofing. With the roof pitched at 50 degrees, the depth of the plan creates an uneconomically large roof space, and therefore the temptation to bring down the eaves...
level and put the upper storey in the roof. More often, the solution adopted is to slacken the roof pitch to an extent uncharacteristic of traditional buildings. The traditional solution to the deep plan is to use parallel roof spans.

Deep plan terraces are best avoided altogether, as the resultant narrow frontage to the dwelling means less frontage width is available for enclosing urban space, and rear gardens have to be inordinately long and thin to provide the minimum required area. However, if deep plan terraces are unavoidable, the gable ends should be concealed or dealt with as described on page 39.

Sometimes the deep plan results from the placing of small dwellings back to back. This is seldom a satisfactory solution, due to the lack of a private garden side to the dwelling, the need to bring car parking close to both sides of the building, and the impossibility of joining such a block to other buildings due to there being windows on all sides. Small dwellings are therefore better arranged in normal terraces.

The placing of flats back to back results in the same problems of wide gable ends and difficulty in joining blocks together to enclose space. Furthermore, a block of flats with aspects in all directions increases problems of overlooking. Blocks one flat deep are thus a better and more flexible solution.

If roads, car parks and access are located on both sides of a block of flats, this can result in a lack of screened amenity space suitable for sitting out. Sufficient space should be provided adjacent to the building on at least one side for usable amenity area.
Normally, roofs should be pitched at about 50 degrees over spans not exceeding 5 m (see page 37), in order to conform to the traditional Essex roofscape. Such roofs look better gabled than hipped. The use of hips on both ends of a house gives it a suburban look and makes it difficult to integrate into the street scene. Hips should therefore only be used sparingly, e.g. on the rear end of a cross wing, or on a freestanding house. A hipped roof on the end of a terrace will lead the eye round and provide continuity into the adjoining street.

Exceptionally, roof pitches in the range 35° - 40° may be used, e.g. for a rear lean-to or a deeper plan house (but see pages 37 and 38). In the latter case, this roof pitch should only be used with either a wide eaves overhang or a parapet.

Furthermore, this roof form should be used in conjunction with substantial chimney stacks centred on the ridge line (see page 48). If the stack does not occur on the gable end, then it should be centrally positioned and the gable should instead be replaced by a hip with a wide eaves overhang. Centrally placed windows on the end elevation can help break up the width.

In the case of a longer terrace, or the important exposed end of a deep plan house with 36° - 40° pitched roof, the treatment of the gable end may be strengthened by brick relief detail to give the impression of a pediment resting on corner pilasters. These measures bring such a building within the vocabulary of forms typical of the nineteenth century and frequently encountered in Essex. In such cases only slates should be used. It may be preferable to conceal an otherwise unsightly wide gable end by a front-to-back cross wing at right angles presenting a narrow gable to the street.
Internal Space Provision

It is important that new houses do not, due to their size or plan form, become obsolete before their constructional life expires. This possibility can be reduced by providing adequate space within the new house at the outset. Whilst it is recognised that the market at the time of initial sale will be the main determinant of acceptability of space provision, it is prudent to have regard to various guidelines. The NHBC, for example, stipulates that developers must show on plans that bedroom furniture can be accommodated. The range of dwelling sizes recommended in the Parker Morris Report "Homes for Today and Tomorrow", produced some 35 years ago, is a good indication of desirable space standards, even though the majority of housing built since has been at a reduced level of space provision. It should be noted that Parker Morris assumed that all two-bedroom and smaller dwellings would be flats. The Parker Morris standards are reproduced for reference in Appendix A.

Extendable Houses

Whilst the owners of any size of house may wish to extend at any time for a variety of reasons, planning authorities are particularly concerned about providing for the possibility of extending small dwellings in order to prevent obsolescence in the face of future rising expectations.

For all two-bedroom and smaller houses, applicants must indicate whether or not the house is extendable. If the house is not extendable the initial planning consent will be conditional on the withdrawal of the householder's right to extend within the limits of the General Permitted Development Order. If the house is extendable the applicant must indicate, as part of the initial planning application, how the house may in the future be extended without problems to neighbouring dwellings and curtilages or unacceptable loss of garden area.

A ground level, rear extension is most easily accommodated without neighbour problems or loss of daylight to the existing house interior if the original house has a wide frontage and shallow plan.

The Building Research Establishment’s report "Site Layout Planning for Daylight and Sunlight" 1991 suggests that obstruction of light and outlook from an existing window is avoided if the extension does not result in the centre of the existing window being within a combined plan and section 45 degree overshadowing zone.

A loft extension can only be provided without unacceptably bulky dormer structures if the original roof is steeply pitched (45 degrees or more), and of purlin rather than trussed rafter construction, and the stair rises in the centre of the plan rather than under the eaves. The stair is likely to have to be contained within a fire-protected compartment when the loft extension is carried out.

Dormers

Dormers in new housing often result from the attempt to provide habitable accommodation within the roof space. This makes them over-dominant in the composition. It is often preferable to include this accommodation within
the main volume of the house by raising the eaves level. Dormers should normally be a minor incident in the roof plane. Their purpose should be to light the roofspace, not to gain extra headroom over any great width. They should not be located close to verges or hips and should have gabled, catslide or flat lead roofs. Rooflights should only be used sparingly and should appear on rear elevations only and not in conjunction with dormers.

**Sound Insulation**

Residents must be protected from extraneous noise so that they can sleep, rest and engage in normal domestic activities in satisfactory conditions. Extraneous noise may be due to external sources: from aircraft, traffic or nearby industry. It may be airborne sound from neighbours, or it may, in the case of flats, be structure-borne impact sound from neighbours on an upper floor.

**Airborne noise from neighbours**

The Building Regulations recommend various forms of party wall which, when tested, achieve a minimum weighted standardised noise level difference (DnT,W) of 49dB and an acceptable mean of 52-53dB between neighbouring premises. According to the Construction Industry Research and Information Association's report "Sound Control for Homes" 1986, external walls typically reduce outside noise by 34dB(A) though by increasing their specification they can be improved to 40dB(A). Designers should aim to increase the specification of party walls permitted by the Building Regulations so that their performance is equivalent to the house being detached.

It is also prudent to zone the rooms of adjoining houses so that, for example, living rooms, stairs and toilets do not abut neighbouring bedrooms.

**Impact sound from neighbours.**

The Building Regulations recommend various forms of party floor construction for flats which, when tested, achieve a minimum weighted standardised impact sound pressure level (L1nT,w) of 65dB and an acceptable mean of 61-62dB. Clearly there is more limited scope than with party walls for improving the specification to perform equivalent to a detached dwelling. However, the need to zone rooms of dwellings above and below to avoid incompatible juxtaposition is even more crucial.

**Placing of Openings**

The best solution for the front elevation of the average medium-to-narrow frontage house is a symmetrical pattern of openings arranged around an opening placed on the central axis, preferably the front door. This arrangement provides a tightly ordered grouping of features and a strong visual presence and is particularly crucial where the front elevation consists of a single gable.
Front-facing gables containing windows are a welcome and enlivening feature of many houses. Also, narrow fronted houses often take the form of a front-facing gable end. However, there is a temptation to make maximum use of the volume thereby created by splitting the gable into two rooms, each with a front-facing window. The resultant pair of windows creates an uncomfortable duality either side of the gable axis which is not traditional. The effect is even worse if the windows are of unequal size and spacing.

Traditional buildings in the region normally only have one room in the gable end with a single, centrally placed window which coincides with and reinforces the axis of the gable, and this practice should be followed in new building. If a second room is unavoidable the window of the larger room should be centrally placed on the gable axis and that of the smaller room relocated on to the flank elevation. Alternatively, a wider, mullioned gable window may be used, with the partition of the second room butting up against a mullion.

Departures from strict symmetry are possible as long as the central axis is still strongly emphasised. The worst solution is one that is almost but not quite symmetrical, which is visually irritating, particularly when repeated on a number of houses.

In the case of a wider frontage elevation, the need for a strongly centralised composition is less great, due to the weakening of the implied central axis, and asymmetrical arrangements can look attractive. Even in such cases the front door is the most important element and should form the basis of the pattern. Similarly, when houses are linked in terraces, the elevation encompasses more than one house and therefore greater freedom of composition is possible, each unit forming part of a larger composition.

Whilst the front elevation is obviously more important, the same rules apply to the composition of rear and side elevations, though they may be interpreted in a more relaxed fashion, unless they are publicly visible.

There is a tendency to use an appropriate window for the room it serves, eg small, high level window for a toilet, raised cill for a kitchen, patio door for a living room, regardless of position or the pattern of openings it produces on the elevation. This can create unbalancing effects, such as a false perspective. Randomness of window size and positioning should be avoided, and a coherent pattern of elevational openings created. This is not to say that a composed effect of randomness may not form part of a coherent pattern, however. This is appropriate for a rear rather than a front elevation.

An integral garage can result in a large garage door that dominates the front of the house, compromising the importance of the front door and the relationship of the dwelling to the street, and adding a utility feature to the otherwise domestic character of the front elevation. If the house is narrow-fronted, the effect is even more dominant.
The prominent positioning of garage doors at the end of a cul-de-sac, road junction or bend in a road constitutes a visual downgrading of the townscape just at the point where a strong element, such as a 'landmark' house (see page 13), is required. The solution is to be more flexible in the positioning of garages so that they can be turned in various directions or combined to form larger structures that perform a more positive role in the townscape.

In the case of integral garages in terrace houses, the metal up and over door is a feature of poor visual quality, and a better solution is often to locate the garage in the back garden, with the visitor parking space within a carriage arch under the building. A well designed timber door inset within an opening at least 200 mm deep is also an acceptable solution.

Solid and Void

Normally, in the case of masonry buildings, the total area of window and door openings should be less than the area of solid wall. Openings should be arranged so as to emphasise the visual strength of the wall by allowing as wide a solid pier as possible between openings, and keeping openings as far away as possible from the corners of the building to give an impression of solid corner buttressing.
This approach can be varied with a timber framed building where an impression of lightness is appropriate. In such cases, the module of the frame should determine the positioning of the openings.

**Balance**

In order to achieve an effect of visual repose, the directional emphasis of an elevation should be counteracted by the directional emphasis of the openings within it. Thus a horizontally proportioned elevation should contain vertically proportioned window openings, whilst a vertically proportioned elevation should contain horizontally proportioned window openings.

A square proportioned window, though it attracts the eye, is neutral and imparts no directional emphasis, but, for example, when used on an upper storey above vertically proportioned window openings, the vertically proportioned windows below will suffice to balance a horizontally proportioned facade. Where a horizontally proportioned window opening is essential, it may be placed in a projecting part of the facade, such as a wing or gable, which itself has a vertical emphasis to balance the emphasis of the window, or modified to provide a vertical element.

**Windows**

For a fuller treatment of this subject, see Essex County Council’s publication ‘Timber Windows’.

Unevenly subdivided windows can disrupt the balance of a well-composed elevation (see preceding paragraph). Window subdivisions should be disposed symmetrically about the horizontal and vertical axes of the openings. Large, unsubdivided panes of glass should not be used, as they distort the visual scale of the building.
The use of a regular pane size for all windows can help unify otherwise discrepantly sized windows. Conversely, variation of pattern of subdivision can highlight particular parts of the elevation, eg the central axis of a gable. All windows and doors should be of painted timber, in keeping with the building traditions of Essex. The drab effect produced by stained joinery should be avoided. Microporous paints, where used, should be of high build type.

Wide patio doors can be a disruptive element in an elevation, whether front or rear, creating the effect of a void. They should be no wider than 1.5 metres and located under a projecting first floor bay or, in the case of a framed building (see page 43) may form part of a larger glazed area. Subdivided french doors are more flexible in their use, but are best located on a central axis or on a projecting or receding part of an elevation not shared with another window.

An overhanging first floor or jetty is a useful device which has the effect of visually separating each floor of a house, allowing more flexibility in the pattern of fenestration (see page 41). Houses, or parts of houses, that rise to three storeys are useful ingredients in the townscape. They can enclose space, terminate a view or add variety.

Present day requirements have led to a tendency to group a number of single storey elements outside the main, two-storey volume of the house around the entrance. These may include an enclosed porch, bin store, cloakroom and meter cupboards. Whilst enclosed porches can be a buffer against the

**Modelling**

The three-dimensional modelling of buildings by set-backs, projecting bays or gables should be manipulated in order to play a deliberate role in the street scene (see pages 21 and 23). It also contributes the effects of shadowing and the play of light.
weather and traffic noise, and can reduce heat loss, traditionally extra appendages were added to the rear, not the front of the house, and current practice compromises the clarity of the dwelling and its relationship to the street. Instead these elements should be planned to fall within the main, two-storey volume of the house, or else to the rear. Clearly, this is not so crucial in low density situations where the house does not relate so closely to the street.

Appropriate Use of Materials

Facing and roof materials should be selected from the range of regional materials characteristic of Essex, or, of that part of Essex where the project is located. This means using those materials present on pre-20th century buildings in a locality. The traditional range includes red, yellow stock and white gault bricks, smooth rendering, black or white painted horizontal weatherboarding, plain clay tiles, clay pantiles, slates and thatch. The use of clay pantiles should be limited to single storey ancillary buildings.

It is appropriate to have different facing materials on different houses in a development, and to change materials between parts of a house. However, feature panels of a different material, eg. false half timbering or vertical tile hanging, are not appropriate and furthermore these materials are not characteristic of Essex.

Any changes in facing material on a house should occur in a logical fashion, eg from one storey to another or to articulate a part of the structure, a front facade, or an architectural feature, such as a gable triangle, a bay window or a plinth. Constructional elements such as lintels and plinths can also be enhanced by picking out in a different material, or by decorative detail. Material changes and detailing should be used in such a way as to explain the building.

Historic streets in Essex towns and villages invariably have a majority of rendered houses, and if, as is desirable, the character of historic settlements is to be reproduced in new development, this proportion of rendered houses should be perpetuated.

Appropriate Detailing for the Materials Used

For a fuller treatment of this subject, please refer to Essex County Council’s Design Guide Practice Note No. 2, Building Details.

Detailing should be used which emphasises the character of the material and has often evolved traditionally. The solidity of brickwork should be expressed by inserting doors and windows within
openings by at least a half brick depth and using sub-cills. Openings should have an arch or lintel which appears adequate to carry the load of the brickwork above. A lintel may be picked out in a different material. The form of the building may be emphasised by string courses, plinths and projections at the eaves. Variations in bond and colour can be used to decorative effect. Corners and openings can be emphasised by quoins and window surrounds in a different colour or material.

Rendered or boarded timber framed buildings should have windows and doors near the face of the wall surface to express the thinness of the construction. Painted timber architraves around the openings and pentine board heads will further emphasise this character.

Buildings of rendered blockwork may follow one of two approaches - either to reflect the appearance of a rendered timber frame building with appropriate detailing, ie without exposed brick detailing, or to appear to be of masonry, with suitable heavy window heads and cills and deep opening reveals. Ashlar false joint markings will further enhance this effect.

Where plain clay tiles are used, roofs must be of 50 degree pitch, whilst in those cases where roofs are in the range 35-40 degrees, only slates should be used, or clay pantiles in the case of single storey structures and outbuildings. Open soffit eaves details are preferable to boxed eaves, which produce a heavy verge detail that contradicts the expression of the roof plane. Parapetted gables and eaves are possible alternatives.

Chimneys

Chimney stacks are commonly found on older buildings and help to punctuate rooflines and provide visual interest. For the purpose of keeping open the choice of fuel, houses should be provided with Class I flues and chimneys. Traditionally, chimneys play an important architectural role in the composition of houses, and should therefore be of suitably massive construction. This will also enable them to contribute to the structure of the building. They should be positioned on the ridge line of the roof, centrally on a gable end, or against an outside wall, and should have pots. In the case of small dwellings without fireplaces, gas flues or soil and...
vent outlets can be combined into chimney structures.

On flank gable ends, chimney stacks should either be flush with the wall or else project sufficiently that the stack has the visual strength to appear capable of standing up on its own.

**Porches**

Open porches and hoods are preferable and are easier to assimilate than enclosed porches (see page 45). A pitched roof porch should project from the building by at least the width of its span. Obviously this could be a cumbersome element on a small elevation. Gabled and flat topped hoods are other possibilities, but lean-to and flat topped enclosed porches detract from the form of the house and are undesirable. A lean-to enclosed porch with side entry may, however, be acceptable on a longer, asymmetrical facade.

**Other Details**

Over-use of 'skin-deep' detail such as applied gables and oriel windows of minimal projection should be avoided. If balconies are provided, they should be proper accessible balconies or full height, inward opening doors with a balustrade in front, not 'clip on' metal structures in front of waist-high windows. Bay windows should be substantial, preferably storey-height elements (see pages 21 and 45).

Vent pipe outlets in roofs should either be grouped and incorporated in chimney features (see page 48) or located on rear slopes. Soil and waste plumbing should be run internally and not appear on the outside of buildings. Grey rainwater goods should be avoided, and black used. Meter cupboards and service intakes should either be located out of sight on flank elevations, in ground level chambers, or accommodated in purpose-made joinery that fits in with the pattern of doors and windows on the elevation.
Supply and disposal services are to be provided in a manner that is technically and visually satisfactory, ie both inconspicuously and accessibly. They are to be considered early in the design process as an integral part of a housing layout, and statutory undertakers and other service suppliers are to be consulted at an early stage.

The economic use of space in a layout means that underground services will almost inevitably be located under roads and footways, and indeed the National Joint Utilities Group’s (NJUG’s) publication “Provision of Mains and Services by Public Utilities on Residential Estates” 1979 recommends as a ‘general aim’ that services should be laid under publicly adopted areas for ease of access for maintenance. Utilities prefer to avoid the necessity to negotiate easements across land controlled by private householders.

**Routeing of Underground Services**

**Carriageways**

Generally, in the laying out of services sewers take priority. As space under footways is limited, sewers will normally be located under carriageways.

**Footways**

NJUG’s publication “Recommended Positioning of Utilities, Mains and Plant for New Works” 1986 indicates that electricity, water, gas, telecommunications and cable TV services can be accommodated in a 2 m wide strip under a footway, including space for lighting columns. If lighting is accommodated on the face of buildings or outside the footway, 1.8 m will suffice. In the case of narrower footways it is possible for some of the services to be routed under the footway on the other side of the road. A common service trench is an efficient way of accommodating services and may save space, if the co-operation of the various utilities can be secured.

In addition to the above-mentioned services, telephone lines from additional service suppliers and district heating may have to be accommodated. Buildings near any service mains should have sufficiently deep foundations not to impose any structural load on the mains.

Overhead distribution of electricity or telecommunications is unacceptable in planning terms, and a condition to this effect will normally be necessary on the planning permission (See Appendix D).

**Verges**

Verges alongside roads, whether publicly adopted or private, should be reserved for tree and other planting, and must therefore be kept clear of underground services.

**Public Open Space**

If a sufficiently large area of publicly adopted space is available alongside a significant length of road, consideration could be given to locating sewers under it to avoid encumbering the carriageway. They should be located in such a way as not to prevent the proper planting of the open space.

**Shared Surface Streets**

As there is no separate footway in such streets, care needs to be taken to group services so that excavation for maintenance does not block the street. In those cases where there is a delineated pedestrian margin, this is the correct location for underground services. Multi-way ducts and/or jointing chambers may be required, depending on the policy of the individual utilities.

**Shared Private Drives**

The developer must negotiate the system of supply with the individual utilities, agree rights of access and apportion any additional costs. Easements with individual householders should be avoided, and any general easements should be entered in the title deed of all the properties sharing the access.

**Service Intakes to Dwellings**

As required on page 49, meter cupboards and service intakes should either be located out of sight on flank elevations, or in ground level chambers, or should be accommodated in purpose-made joinery that fits in with the pattern of doors and windows.
on the elevation. All intakes apart from gas should be run within the building and not be visible on the exterior. These requirements should be covered by conditions on the planning permission (see Appendix D for recommended conditions).

Substations and Governors

Electrical substations and gas governors should be housed in purpose-made buildings designed and located to blend in with the adjoining housing. This will also cut down noise and smell to neighbours.

Electrical substations and gas governors must be shown on planning applications, and it is recommended that a condition be imposed withdrawing utility companies’ permitted development rights in such cases (see Appendix D).

Public Call Boxes

A large development may well justify one or more telephone call boxes. These should be located at nodal points in the street system where there is a higher level of pedestrian movement, and readily visible. At least 1.75 m width of footway should remain unobstructed after installation of the call box.

Post boxes

Consideration should be given to building post boxes into walls rather than using free standing boxes. Delivery holding boxes should be integral with postal collection boxes, not strapped to the side.

Television and Radio Aerials and Satellite Dishes

In order to reduce TV and radio aerial clutter, developers should consider either a communal aerial with wired supply to each dwelling, or covenants requiring aerials to be located in lofts. A block of flats should always have a communal aerial and satellite dish if cable TV is not available, and a condition should be attached to the planning permission to this effect (See Appendix D).

Cable networks, in those areas where they are available, supply all channels currently available by conventional aerial or satellite dish, and developers should combine provision of cable TV with covenants banning both aerials and satellite dishes. In those areas where cable distribution is not available satellite dishes should be located as inconspicuously as possible (see the DoE publication “Householders’ Planning Guide for the Installation of Satellite Television Dishes”). This means that dishes should preferably be of dark colour mesh and must be kept off the front of the dwelling and roofs. A condition should be attached to the planning permission to this effect (see Appendix D).

Street Name Plates and Markers

These are best fixed to walls and buildings where they can be clearly seen. Free standing street furniture and statutory undertakers’ markers should be kept to a minimum.

Refuse Collection

Refuse freighters will circulate on all parts of the adopted road system, but not on private drives. In the case of mews court culs-de-sac, Type 8 (see page 62), these will enter in reverse gear and not turn. Refuse collection will be made only from those dwellings within 25 metres of an adopted road. In other cases a shared bin collection point screened by an above-eye-level wall will be necessary, located within 25 metres of an adopted road. In the case of terrace houses, bin collection points or accesses should be provided to the rear of properties rather than at the front.

ACCESS

Buses

In the interests of providing access for those without the availability of a car and of reducing the need to use motor cars, it is important that the accessibility of residential areas by public transport be improved. This can be achieved by the careful siting of residential development through the Local Plan, but in the case of larger developments it will be necessary for bus routes to enter and serve new residential areas. This must be taken into account in the planning of such developments.

Types of Bus and Bus Stops

Since bus deregulation, routes do not have to be licensed and, with the increasing use of smaller buses, a bus can use almost any road. Nevertheless, it is possible to plan the layout of a residential area with the ease of operating a bus service in mind. It is a reasonable assumption that larger, conventional buses will operate on existing roads and on type 1 and 2 roads (see page 57) with bus stops at approximately 4 to 5 per mile (2 to 3 per kilometre). Smaller buses will operate within 20 mph (30 kph) zones on type 3 roads (see page 58) probably on a ‘hail and ride’ basis, i.e. without fixed stops. Where fixed bus stops are provided, stops on opposite sides of the road should be staggered so that buses travelling in opposite directions stop ‘tail to tail’ and move off away from each other. The road system likely to be used by buses should be laid out in such a way that no dwelling is further than 400 metres from either a bus stop or a ‘hail and ride’ route.
**Routes and Termini**

Type 3 roads (see page 58), which are most likely to be used by buses, should be laid out to provide a reasonably direct route in and out of the area, passing higher density residential development, schools and neighbourhood facilities. In places where it is desirable to offer cars a less direct route, a bus-only link is a possible solution. It is preferable for a bus route to be arranged as a loop so that buses do not have to turn. However, if a terminus is unavoidable, a full-size bus requires a roundabout of 26 m outside diameter and 14 m inside diameter, whilst a small bus can negotiate a normal mini-roundabout. Whether the route is looped or has an end terminus, a layover point is necessary at the end of a journey. This should be in the form of a lay-by of length appropriate to the type of bus, located preferably at a neighbourhood centre or community facilities. Care should be taken to avoid nuisance or loss of privacy to residents at such locations. Bus shelters of a design acceptable to the local authority should be provided at all those bus stops. These shelters are to be served by underground cabling for passenger information indicators.

**Pedestrian and Cycle Movement**

Within new residential areas, pedestrian and cycle movement should be convenient, safe and pleasant. Direct routes should be provided to local facilities and adjacent neighbourhoods in such a way that it is more convenient and attractive to walk or cycle than to drive to such destinations. The aim should be to discourage the use of the car for local trips and to encourage walking and cycling between homes and the local facilities residents need to visit regularly.

The policy of subordinating the speed and throughput of traffic to the environmental requirements of the space within which the road is located, together with the use of 20 mph (30 kph) zones, will result in narrower, slower roads and thus a more pedestrian and cyclist-friendly environment. There should therefore be no need for segregated spine footpaths, and indeed these can present opportunities for crime, either against pedestrians or against properties backing onto the footpath. Instead pedestrian routes should be mainly along residential roads, with occasional short links to give pedestrians and cyclists a preferential direct route. Wherever possible pedestrian and cycle routes should be overlooked by the fronts of dwellings.

**Provision of the Service**

Bus operators will be required to start their services as soon as the road carrying the bus route is in place. Local authorities or developers may have to subsidise early provision of a bus service so that it is available when the majority of residents move in and the habit of using the service can be established at the outset. Developers of large residential areas must show proposed bus service provision in their planning application.

**Footways to Roads**

The width of these will vary according to the type of road, but normally is sufficient to allow two people to pass. It is also possible, for a length of 8 metres or less, to narrow the footway to a single pedestrian width of 1 metre (minimum headroom 2.25 m), provided such a ‘courtesy section’ is positioned so that pedestrians are not induced to step into the carriageway.

Lower categories of road that are less trafficked, such as Types 5 and 7 (see pages 59 and 61), have a pedestrian margin rather than a delineated separate footway.

**Pedestrian and Cycle Links**

Pedestrian and cycle links should be used to create preferential routes through a residential network,
to link to adjacent existing residential and other areas in such a way as to improve accessibility without introducing extra vehicular traffic, and to provide multiple accesses to a residential area from a major road, rather than funnelling pedestrians and cycles into the site at one point shared with a vehicular access.

Pedestrian and cycle links should be a minimum of 2.5 metres wide if the surface is shared between pedestrians and cyclists, or 3 metres if pedestrians and cyclists are separated. Separation should be by a 25 mm kerb or by a tactile white line. Where the link is bounded by a building, wall or fence it should be widened on that side by 0.5 m. There should be ‘parallel’ tactile ribbing at the ends of the cycle portion and ‘right-angled’ ribbing at the ends of the pedestrian portion. Other design solutions may be acceptable, subject to approval by the highway authority.

A pedestrian and cycle link should be as short as possible, with intervisible ends, and fronted by dwellings for a good part of its length. Pedestrian and cycle links should be regarded as part of the street system and could be run parallel to private drives in cases where vehicular access to frontage dwellings is required.

**Segregated Cycleways**

For strategic links between various parts of a town, or where a cycle route runs alongside road Types 1 and 2, which are outside 20 mph (30 kph) zones and are likely to be more heavily trafficked (see page 57), a segregated parallel cycleway may be desirable. This should be 2 metres wide and separated from the carriageway by a 3 metre wide tree planted verge. If combined with a footway, the design standard should be as for a pedestrian/cycle link with pedestrians and cyclists separated (see above).

**Crossings**

Where a cycle route crosses a road Type 1 or 2, a dropped kerb is necessary at the road crossing, together with a staggered arrangement of barriers to persuade cyclists to slow up. A space of 1.5 metres is required between the barriers to allow the passage of wheelchairs. Where peak hour two-way traffic flows exceed 500 vehicles per hour a signal controlled crossing will be necessary. In such cases staggered barriers are not required.

Where a cycle route crosses a road of Type 3 or below (see pages 58 to 63) the cycle route should have priority over road traffic, and the crossing should be designed as a speed restraint measure to road traffic. This is to be achieved by the surface material of the cycle route continuing across the carriageway and the road approach to the crossing being ramped up 75 mm over a length of 1100 mm, similar to a speed table (see page 67). Signing will be necessary on the approaches to the crossing, even within a 20 mph (30 kph) zone.

In all cases where a pedestrian/cycle route meets a highway, footway or another pedestrian/cycle route, 1.5 m x 1.5 m sight splays are required.

**Vehicular Movement**

Within new residential areas, vehicular movement should be convenient, safe and pleasant, but vehicular access is to be provided for in such a way as to be consistent with the achievement of an attractive environment and the needs of the pedestrian or cyclist who have to share the same space.

Through traffic is to be excluded from new residential areas, and the layout and attractiveness of the environment should be such as to discourage the use of the car for local trips and encourage walking and cycling. To achieve these aims, the environmental requirements of the urban space within which each road is located should determine the width and speed of alignment of the road. This means that the character and pleasantness of the space takes precedence over
the speed and throughput of traffic to be carried by the road contained within it. By ‘calming’ traffic in residential areas in this way, there should be a corresponding benefit in increased pedestrian safety and thus the pleasantness and usefulness of the environment to the pedestrian.

All new residential areas should be divided up into elements not exceeding 700 dwellings. Each of these elements, and any new development less than 700 dwellings in size and containing a road over 100 m in length is to be served entirely by roads of a design speed of under 20 miles per hour (30 km per hour).

Rather than a hierarchy of road types, a number of adoptable road types are recommended here which comply with this requirement. In order to restrict speed, it is preferable to use changes of alignment, ie bends, rather than physical obstructions, such as speed humps and chicanes, which should only be used in those less frequent cases where straight sections of road are required for urban design reasons.

It is recognised that a very extensive 20 mph (30 kph) network could be slow and frustrating to drive through and could slow up access for the emergency services. Such networks should therefore be designed in such a way that it is not necessary to travel farther than a quarter of a mile (0.4 km) through the network to reach a feeder road offering a more direct route out. There will also be larger roads which link groups of residential areas of 700 dwellings.

Generally, for the reasons stated on page 11, there should be a tendency to construct networks from linked roads rather than culs-de-sac, which should be limited in length and number and restricted to those parts of a site which cannot be served in any other way.

Whilst the road types and configurations recommended here will be adopted for the purposes of maintenance, it is open to planning applicants to propose other solutions which achieve the same purposes and these will be considered on their merits.

**Access to Non-Residential Uses**

Non-residential uses such as schools, churches, community halls, shops and small businesses may be located within a 20 mph (30 kph) zone but must be served by a road no smaller than Type 3 (see page 58). Businesses likely to be regularly serviced by vehicles larger than 7.5 t, eg a retail store or supermarket, must be served on their delivery side by a road no smaller than Type 2 (see page 57), or else a 6 m wide one-way loop road.

Schools should not be located on a road terminating in a cul-de-sac. In addition to staff car parking they should be provided with adequate parent car

</table>
parking space clear of the highway and enough overspill parking space (eg on playgrounds) to cater for out-of-hours community activities. There should be space for at least one 50-seater coach to park clear of the highway, and secure cycle parking should be provided.

Clearly general and special industrial uses will not be appropriate in or near a residential area, but other businesses will be considered on their merits dependent on size and traffic generation. Parking and service areas for non-residential uses will not be adoptable by the highway authority, but where they are shared by a number of small retail or business users and not frequented by vehicles larger than 7.5 tonnes, developers should consider fronting some buildings on to them and encouraging through pedestrian movement so that they do not become enclosed areas that are liable to criminal activity.

Parking provision for non-residential uses is covered by ‘Standards for Car Parking in Essex 1987’ which will be interpreted according to how accessible uses are by means other than by car, and whether trips are shared between a number of adjacent uses or peak at different times. As the purpose of locating non-residential uses in or adjacent to a predominantly residential area is to encourage trips by means other than by car, car parks should not be placed in front of the main entrance but at the side or rear where they will not form an obstacle to pedestrian or cycle access. Larger car parks, eg for a retail store, should be fragmented into a number of smaller car parks and generously tree-planted. Secure cycle parking for a minimum of 25 per cent of employees plus an allowance for visitors should be provided in a location more convenient than the car park to the main entrance to premises.

**Type 1 Local Distributor**

These are local, multi-purpose roads which give access to residential areas and other land uses, and form part of the local county road network*. Built frontage is required to these roads, i.e. houses should face the road rather than turn their backs. Access to frontage dwellings should be by parallel access roads or shared private drives reached either from the rear or from the local distributor road itself at a minimum spacing of 120 metres. In the case of parallel access roads, these could form part of a continuous cycleway following the Type 1 road. Alternatively a segregated cycleway may be provided (See page 54).

Pedestrian and cycle routes should cross these roads where necessary, so that the road does not act as a barrier to local cross movement. (See page 11).

A carriageway width of 7.3m, or 6.75m with bus lay-bys, is required. A 2m wide footway is required each side of the carriageway, separated from it by minimum 3m wide verges which are to contain tree planting.

The design speed is 50 kph (30 mph), and this is to be ensured in the vicinity of residential areas by bends of a centreline radius of 90 metres separated by a straight length of 36 metres. Longer straight sections or less sharp bends will not be allowed in these situations. Elsewhere the normal centreline radius will be 200 metres.

This road type may only take access from an existing county road or another Type 1 road.

The design of a junction with an existing county road will be to the requirements of the highway authority. Other junctions require a minimum kerb radius of 10.5m. The minimum length of minor road from the junction required to be straight is 30 metres from the channel of the main road. Sight lines of X distance 6m by Y distance 90m are required, but could be reduced where traffic speeds are below 30 kph (20 mph).

The maximum gradient should be in the order of 5%.

**Type 2 Link Road**

These are roads which link neighbourhoods within a large residential area.

Built frontage is required to these roads. Direct frontage access to dwellings is allowed, but egress on to the road must be in forward gear only. 1.5m x 1.5 m pedestrian/vehicle sight splays are required at egresses (see page 70) and 1.5m x 2m where the egress meets the carriageway.

A carriageway width of 6.75m is required. A 2m wide footway is required each side of the carriageway, separated from it by minimum 3m wide verges which are to contain tree planting.

The design speed is 50 kph (30 mph). The minimum centreline bend radius is 30m and the maximum 70m.

---

*N.B. It should not be assumed that all existing county roads in urban areas that serve mixed land uses necessarily count as Type 1. Many of them have frontage access and frequent junctions and it may be appropriate for new development to conform to the existing pattern.*
This road type may take access from an existing county road, a Type 1 road or a Type 2 road.

The design of a junction with an existing county road will be to the requirements of the highway authority. Other junctions require a minimum kerb radius of 10.5m.

The minimum length of minor road from a junction required to be straight is 22 metres from the channel of the main road. Sight lines of X distance 6m by Y distance 90m are required where the major road at the junction is a Type 1. Elsewhere a Y distance of 60m is required. Reduced Y distances are possible where traffic speeds are below 30 kph (20 mph).

The maximum gradient should be in the order of 6%.

**Type 3 Feeder Road**

These are feeder roads within a 30 kph (20 mph) network serving a maximum of 700 dwellings. No part of a residential area should be farther than 0.4 km (a quarter of a mile) from a 3 or higher category road. These roads offer a direct route out of a 30 kph (20 mph) network.

Direct frontage access to dwellings is allowed, but within 30 metres of a junction egress to the road must be in forward gear only.

1.5m x 1.5m pedestrian/vehicle sight splays are required at egresses on to this road type (see page 70), and 2m x 33m where the egress meets the carriageway.

A carriageway width of 6 metres is required. Where this road type serves fewer than 400 dwellings in the case of a link or loop or 200 dwellings in the case of a cul de sac the carriageway width may reduce to 5.5 metres. A minimum 1.8 m wide footway is required each side of the carriageway. If a verge for tree planting is desirable, this should be at least 3m wide and located between the footway and the carriageway.

The design speed is 30 kph (20 mph), and this is to be ensured by speed restraint measures, (see page 65). The minimum centreline bend radius is 20m unless a tighter speed restraint bend is being used. The maximum centreline bend radius is 70m.

This road type may take access from an existing county road, a Type 1, Type 2 or 3 road.

The design of a junction with an existing county road will be to the requirements of the highway authority. Other junctions require a minimum kerb radius of 6 metres.

The minimum length of minor road from the junction required to be straight is 22 metres from the channel of the main road. Sight lines of X distance 2.4m by Y distance 90m are required where the major road at the junction is a Type 1. Elsewhere a Y distance of 60m is required - reduced Y distances are possible where traffic speeds are below 25 kph (15 mph).

The maximum gradient should normally be in the order of 8%, but where the retention of existing topography is desirable, steeper gradients will be considered subject to the use of a special surface finish giving better adhesion.

**Type 4 Minor Access Road**

These are minor roads within a 30 kph (20 mph) network giving direct access to dwellings. Culs de sac may serve as access to not more than 100 dwellings, whilst loops or links (the more usual case) may give access to not more than 200, subject to equal traffic distribution.

A carriageway width of 4.8 metres is required. A minimum 1.5m wide footway is required each
side of the carriageway, or a single 1.8m wide footway if fewer than a total of 25 dwellings are being served. If a verge for tree planting is desirable, this should be at least 3m wide and located between the footway and the carriageway. In the case of a single footway, a 500mm overhang strip is required alongside the opposite side of the carriageway.

1.5m x 1.5m vehicle/pedestrian sight splays are required at egresses on to this road type (see page 70) and 2m x 33m where the egress meets the carriageway.

A clear distance of 6m is required between a parking space abutting the highway and the opposite edge of the carriageway.

The design speed is 30 kph (20 mph), and this is to be ensured by speed restraint measures (see page 65). The minimum centre line bend radius is 13.6m unless a tighter restraint bend is being used. The maximum centreline bend radius is 30m.

This road type may take access from an existing county road, a Type 1, Type 2 Type 3 or Type 4 road.

The design of a junction with an existing county road will be to the requirements of the highway authority. Other junctions require a minimum kerb radius of 6 metres.

The minimum length of minor road from the junction required to be straight is 15 metres from the channel of the main road. Sight lines of X distance 2.4m by Y distance 33m are required. Y distances may be reduced where traffic speeds are below 25 kph (15 mph), and the X distance may reduce to 2m if no more than six dwellings are served.

The maximum gradient should normally be about 8%, but where the retention of existing topography is desirable, steeper gradients will be considered subject to the use of a special surface finish giving better adhesion.

The provision of a ramp or rumble strip at the junction may be required. Also a special surface to encourage slow speeds will be required for the whole length of the road, eg:

- tar spray and shingle dressing
- coloured asphalt
- interlocking concrete or clay block paving
- granite or artificial setts
- stable blocks

**Type 5 Minor Access Way**

These are minor shared surface roads within a 30 kph (20 mph) network giving access to no more than 25 dwellings in the case of culs-de-sac or 50 dwellings in the case of loops or links (the more usual case), subject to equal traffic distribution. These roads are for use in schemes of a rural or Arcadian character, ie at densities of no more than 8 dwellings per acre (20 dwellings per hectare).

An overall carriageway width of 4.8 metres is required. This may be provided in two alternative ways:-

(i) A vehicle way of 3 metres with a pedestrian margin of 1.8 metres delineated by a row of setts, brick paviers or other suitable demarcation. This margin would be used by pedestrian traffic and for vehicle passing.

(ii) A vehicle way of 3.7 metres with a minimum verge of 1.1 metres (under which services would be located and which would be adopted). The carriageway should widen to 4.8 metres to allow for passing bays where necessary.
1.5m x 1.5m vehicle/pedestrian sight splays are required at egresses on to this road type (see page 70) and 2m x 33m where the egress meets the carriageway.

Where houses are located at the edge of the vehicle way, they should be set back 500mm and protected by bollards.

A clear distance of 6m is required between a parking space abutting the highway and the opposite edge of the carriageway.

A parking space convenient to the entrance and within the curtilage of the dwelling must be provided for each dwelling served by this road. Where the carriageway width is reduced to 3.7 metres it would be advisable for off-street parking within the curtilage of the dwelling to be provided for delivery lorries, etc. A swept curve at the access to each plot will also be necessary.

The design speed is 30 kph (20 mph), and this is to be ensured by speed restraint measures (see page 65). The minimum centre line bend radius is 13.6m unless a tighter speed restraint bend is being used. The maximum centreline bend radius is 30m.

This road type may take access from an existing county road, a Type 1, Type 2, Type 3, Type 4 or Type 5 road. The design of a junction with an existing county road will be to the requirements of the highway authority. Other junctions require a minimum kerb radius of 4 metres.

The minimum length of minor road from the junction required to be straight is 15 metres from the channel of the main road. The first 12m must be of 4.8m width, narrowing over a length of 5m if required. This initial length must be provided with a separate footway of 1.8m width on one side of the carriageway. A ramp or rumble strip must be provided. Sight lines of X distance 2.4m by Y distance 33m are required. Y distances may be reduced where traffic speeds are below 25 kph (15 mph), and the X distance may reduce to 2m if no more than six dwellings are served.

The maximum gradient should normally be about 8%, but where the retention of existing topography is desirable, steeper gradients will be considered subject to the use of a special surface finish giving better adhesion.

A special surface to encourage slow speeds will be required for the whole length of the road, eg:
- tar spray and shingle dressing
- coloured asphalt
- interlocking concrete or clay block paving
- granite or artificial setts
- stable blocks

**Type 6 Minor Access Way**

These are minor roads within a 30 kph (20 mph) network giving direct access to dwellings. Culs de sac may serve as access to not more than 25 dwellings, whilst loops or links (the more usual case) may give access to not more than 50, subject to equal traffic distribution.

1.5m x 1.5m vehicle/pedestrian sight splays are required at egresses on to this road type (see page 70).

A carriageway width of 4.1 metres is required. A minimum 1.35m wide footway is required each side of the carriageway, capable of carrying overrunning vehicles.

A clear distance of 6m is required between a parking space abutting the highway and the opposite edge of the carriageway.

The design speed is 30 kph (20 mph), and this is to be ensured by speed restraint measures, (see page 65). Because of the narrow carriageway and over-runnable footways, humps, tables or chicanes will not be practicable for this road type. The minimum centreline bend radius is 13.6m unless a tighter speed restraint bend is being used. The maximum centreline bend radius is 30m.

This road type may take access from an existing county road, a Type 1, Type 2, Type 3, Type 4 or Type 6 road.

The design of a junction with an existing county road will be to the requirements of the highway authority. Other junctions require a minimum kerb radius of 4 metres.

The minimum length of minor road from the junction required to be straight is 15 metres from the channel of the main road. The first 12m must be of 4.8m width, narrowing over a length of 5m. Sight lines of X distance 2.4m by Y distance 33 m are required. Y distances may be reduced where traffic speeds are below 25 kph (15 mph), and the X distance may reduce to 2m if no more than six dwellings are served.

No windows or doors should open outwards or overflow pipes, single storey eaves etc project over the net adoptable area of the road or footway. Where buildings abut the back edge of the footway, street lighting should be fixed to the buildings instead of on columns.

The maximum gradient should normally be about 8%, but where the retention of existing topography is desirable, steeper gradients will be considered subject to the use of a special surface finish giving better adhesion.
The provision of a ramp or rumble strip at the junction is required. Also a special surface to encourage slow speeds will be required for the whole length of the road, eg:

- tar spray and shingle dressing
- coloured asphalt
- interlocking concrete or clay block paving setts
- granite or artificial setts
- stable blocks

The design of a junction with an existing county road will be to the requirements of the highway authority. Other junctions require a constricted entrance enclosed by buildings or walls to a minimum height of 1.8 metres for the first 8 metres back from the footway of the major road (except for the 1.5m x 1.5m sight splays). No doors, gates or other entrances may open on to the mews within this first 8 metres. A mountable kerb and a further ramp of 50mm upstand 6 metres back from the footway of the major road are required, and a 1.5m x 1.5m vehicle/pedestrian sight splay either side of the entrance (see page 70).

The mews is to be straight for 10.5 metres from the junction. At the junction, sight lines of X distance 2.4m by Y distance 33m are required. Y distances may be reduced where traffic speeds are below 25 kph (15 mph), and the X distance may reduce to 2 m if no more than six dwellings are served.

No windows or doors should open outwards or overflow pipes, single storey eaves etc project over the net adoptable area of the mews. Where buildings abut the mews, street lighting should be fixed to the buildings instead of on columns.

The maximum gradient should normally be 8% but, where the retention of existing topography is desirable, steeper gradients will be considered subject to use of a suitable surface finish giving better adhesion.

**Type 7 Mews**

These are minor pedestrian/vehicular shared surfaces within a 30 kph (20 mph) network giving access to not more than 25 dwellings as a cul-de-sac, or 50 as a loop or link (the more usual case), subject to equal traffic distribution. Where garages or parking spaces are located outside the mews and accessed from another road, the number of dwellings served may be increased appropriately, but may not exceed double the numbers shown. No vehicle/pedestrian sight splays are required at egresses on to the mews.

The minimum width should be 5.8 metres of which 1 metre would form an adoptable pedestrian margin delineated by a row of setts, brick paviors or other suitable demarcation. Underground services would follow this strip.

A clear distance of 6m is required between a parking space abutting the mews and the opposite edge of the mews.

The design speed is 30 kph (20 mph) and this is to be ensured by speed restraint measures, (see page 65). The minimum centreline bend radius is 13.6m unless a tighter speed restraint bend is being used. The maximum centreline bend radius is 30m.

This road type may take access from an existing county road, a Type 1, Type 2, Type 3, or Type 4 road.
A special surface is required in order to encourage slow speeds, eg:
- tar spray and shingle dressing
- square paving slabs
- interlocking concrete or clay block paving
- granite or artificial setts
- stable blocks

A minimum 50mm upstand must be provided where planted areas abut the mews surface. Adjacent paved surfaces must be strengthened to take vehicle overrunning, and would not necessarily be adopted by the highway authority.

**Type 8 Mews Court**

These are minor pedestrian/vehicular shared surfaces within a 30 kph (20 mph) network giving access to not more than 25 dwellings as a loop or link, subject to equal traffic distribution, or 12 as a cul-de-sac. Where garages or parking spaces are located outside the mews court and accessed from another road, the number of dwellings served may be increased appropriately, but may not exceed double the numbers shown.

No vehicle/pedestrian sight splays are required at egresses on to the mews court.

The minimum width should be 4.8 metres, and no separate footway is required. A clear distance of 6m is required between a parking space abutting the mews court and the opposite edge of the mews court.

The design speed is 30 kph (20 mph) and this is to be ensured by speed restraint measures, (see page 65). The minimum centreline bend radius is 13.6m unless a tighter speed restraint bend is being used. The maximum centreline bend radius is 30m.

This road type may take access from an existing county road, a Type 1, Type 2, Type 3 or Type 4 road.

The design of a junction with an existing county road will be to the requirements of the highway authority. Other junctions require a constricted entrance enclosed by buildings or walls to a minimum height of 1.8 metres for the first 8 metres back from the footway of the major road (except for the 1.5m x 1.5m sight splays). No doors, gates or other entrances may open on to the mews court within this first 8 metres. A mountable kerb and a further ramp of 50 mm upstand 6 metres back from the footway of the major road are required, and a 1.5m x 1.5m vehicle/ pedestrian sight splay either side of the entrance. (See page 70)

The mews court is to be straight for 10.5 metres from the junction. At the junction, sight lines of X distance 2.4m by Y distance 33m are required. Y distances may be reduced where traffic speeds are below 25 kph (15 mph), and the X distance may reduce to 2m if no more than six dwellings are served.

No windows or doors should open outwards or overflow pipes, single storey eaves etc project over the net adoptable area of the mews court.

Where buildings abut the mews court, street lighting should be fixed to the buildings instead of on columns.

The maximum gradient should normally be 8% but, where the retention of existing topography is desirable, steeper gradients will be considered subject to the use of a suitable surface finish giving better adhesion.

A special surface is required in order to encourage slow speeds, eg:
- tar spray and shingle dressing
- square paving slabs
- interlocking concrete or clay block paving
- granite or artificial setts
- stable blocks.

A minimum 50mm upstand must be provided where planted areas abut the mews surface. Adjacent paved surfaces must be strengthened to take vehicle overrunning, and would not necessarily be adopted by the highway authority.

**Parking Square**

These are pedestrian/vehicular shared surface spaces occurring at intervals within a 30 kph (20 mph) network. The number of dwellings served by a parking square will depend on the size of the space which is not to exceed 50m in any dimension. No vehicle/pedestrian sight splays are required at egresses on to the parking square.
A minimum 4.8 metre wide marked vehicle way is to traverse the space. If the parking square is being used as a speed restraint measure, this vehicle way is to change direction in the square eg. entering in one corner and leaving through the corner diagonally opposite, and may not simply cross the space in a straight line.

A junction of routes may occur within the square, in which case the junction is to be set out with 4 metre radii and 2m X distance sight lines from the minor route. The Y distance need not extend beyond the square. Some kind of central feature should be placed at the centre of the square to aid driver orientation. In the case of a square without a junction, the central feature should be located in the middle of the vehicle way, which should be widened to allow traffic to pass either side. Road markings or arrows or chevrons on the central feature should be used to indicate that traffic is to pass on the left. As a built feature within the highway, a contribution will be required from the developer towards future maintenance of the central feature. In the case of a parking square which is not being used as a speed restraint measure, speed restraints should be used on the approach roads as required for the particular road type.

The parking square is to be directly fronted by buildings, and a 1.5 metre wide pedestrian margin is to be marked out in front of the building facades. This demarcation should be in the form of a different colour of paving and a 15mm upstand channel. The differentiation in colour should extend 5m beyond the parking square on to footways of approach roads. Car parking may be accommodated in those parts of the square not occupied by the vehicle way and pedestrian margin, which should be protected, where appropriate, by bollards. It is likely that half the parking requirement of the frontage dwellings will be accommodated in the square, with the other half between or behind the dwellings.

No windows or doors should open outwards or overflow pipes, single storey eaves, etc, project over the net adoptable area of the parking square. Street lighting should either be fixed to buildings or on columns which should be carefully positioned clear of vehicle manoeuvring areas and protected by bollards if necessary.

A special surface is required in order to encourage slow speeds, eg:

- tar spray and shingle dressing
- square paving slabs
- interlocking concrete or clay block paving
- granite or artificial setts
- stable blocks.

The vehicle way should be demarcated by channels or rows of setts and allowance should be made for overrunning by larger vehicles where bends in the vehicle way are tighter than 13.6m centreline bend radius.

In the case of a parking square which is being used as a speed restraint measure, the vehicular approach from entering roads is to be tabled, i.e. ramped up 100 mm. A parking square may be located on a Type 4, Type 6, Type 7 or Type 8 road.

One-Way Streets

If it is desired to reduce road widths below what they would otherwise have to be, it is possible for any road type of category 3 or below to be used as a one-way street. No more than 100 dwellings should be directly served by a one-way street, as otherwise it can be frustrating for residents at one end of such a street to have to make a long detour.
for a trip that could have been more directly made in the direction against the flow.

For a one-way street, the width of the carriageway can be reduced to 3.7 metres. In every other respect the design requirements are as for the particular road type.

Where a one-way street leaves another road no sight lines are required, but where it joins another road sight line requirements are as they would be for the equivalent two-way road type. Side junctions on to a one-way street need a sight-line in the direction of on-coming traffic only.

One-way streets should be clearly signed as such in accordance with the Traffic Signing Manual 1986, Chapter 3 Part 6 at their entry, exit and side junctions. Where there are long intervals between side junctions there should be reminder signs for the benefit of vehicles joining the street from frontage premises placed alternately on each side of the road at a minimum spacing of 100 metres between signs on the same side. There should be arrows painted on the road surface at 30 metre intervals.

**Shared Private Drives**

**Definition**

Private drives are vehicular and pedestrian access ways not suitable for adoption as highways maintainable at public expense. They may give access to a maximum of five dwellings.

**Access Restrictions**

Private drives may take access from all road types, but in the case of a County road the junction may have to be to the requirements of the

highway authority. Where they take access from Type 1 and 2 roads, turning facilities are necessary in order to enable egress in forward gear. This also applies within 30 metres of a junction on Type 3 roads. On Type 7 and 8 roads private drives may not take access within the first 8 metres of the length of the road.

**Width**

The minimum width for a drive serving a single dwelling is 2.4 metres. A shared private drive off road types 4-8 and off a parking square may also be 2.4 metres wide, but off a County road and road types 1-3 must be 4.1 metres wide for the first 6 metres from the highway, tapering over 6 metres down to 2.4 metres. Normally refuse collection vehicles will not enter private drives, and any dwellings more than 25 metres from the highway will need a bin collection point within that distance. Any dwelling more than 45 metres from the highway will necessitate use of the drive by fire tenders, in which case dimensions must be as indicated under ‘Access for Fire Tenders’, see page 77, and the drive should be capable of carrying a 12.5t vehicle.

The drive in front of a double garage should be the width of the garage or a minimum of 4.8 metres, for a length of at least 9 metres in front of the garage doors.

**Junction Details**

Where a private drive joins a road of types 1-3, a vehicle sight line of X distance 2 metres x Y distance 60 metres from the edge of the carriageway will be required. The Y distance may be reduced where traffic speeds are below 25 kph (15 mph). Where a private drive joins a road of types 4-6, a vehicle sight line of X distance 2 metres x Y distance 20 metres from the edge of the carriageway will be required.

Vehicle/pedestrian sight splays of 1.5m x 1.5m from the back of the footway should be provided on each side of a drive joining road types 1-6 (see page 70). No obstruction over 600mm will be allowed within any vehicle or pedestrian sight splays. Sight splays are not required where a drive joins road types 7 or 8 or a parking square.

**Parking Facilities on Shared Private Drives**

In shared private drives, parking facilities for each dwelling must be provided clear of the shared drive area, turning space, passing bays, etc. It is essential on both single and shared drives that adequate manoeuvring space be provided to allow vehicles to enter and leave all garages and parking spaces with other vehicles parked on all other parking spaces.
**Turning Facilities**

All drives longer than 18 metres should have a turning head equivalent to at least Size 5. Any drive off a Type 1 or 2 road, or off a Type 3 road within 30 metres of a junction, should have a turning head of at least Size 5. A drive to be used by fire tenders must have a turning head of at least Size 3.

**Passing Places**

Passing places will be required on shared drives longer than 18 metres, or on any drive from which ends are not intervisible.

**Alignment**

A drive should meet the highway at an angle such that a car can turn in either direction in one movement. Normally this would necessitate the drive meeting the highway at an angle within 10 degrees of a right angle. Where the drive is to be used by fire tenders, a fire tender should be able to turn in either direction in one movement. Usually the minimum centre line bend radius will be 6 metres, but will need to be 6.55 metres (or 7.75 metres if enclosed by walls) where the drive is to be used by fire tenders.

**Gradient**

The maximum gradient should normally be 8% but, where the retention of existing topography is a consideration, steeper gradients will be accepted subject to the use of a suitable surface finish.

**Surface Finish**

Materials suitable for reducing vehicle speeds and of pleasant appearance should be used, e.g. loose gravel (which should be bound with an approved binder within 6m of the highway), tar spray and shingle dressing, (likewise to be bound within 6m of the highway), coloured asphalt, concrete or clay block paving, granite or man-made setts, cobbles or stable blocks.

**General Design Criteria**

**Speed Restraint**

All new residential developments containing a road system which measures more than 100m from the entrance to the development to the furthest extremity of the road system are to constitute, or form part of a 20 mph (30 kph) zone and will require a Department of Transport Certificate (see Appendix B).

Speed restraint measures are to be used throughout 20 mph (30 kph) zones and do not require warning signs within the zone. Signs (in accordance with DpT Traffic Advisory Leaflet 2/93) and an entrance Gateway are, however, required to indicate to drivers that they are entering a zone.

**Gateways**

A gateway is required at each entrance to a 20 mph (30 kph) zone. The main purpose is to indicate visually to drivers that they are entering a special area. The gateway may consist of a pinch point of buildings or walls approaching the carriageway, or of a physical gateway either arching over the road or taking the form of a pair of substantial brick
piers close to the carriageway. The footway may pass either through the gateway or around it. In the case of a physical gateway, structures should be designed to withstand vehicle impact and should provide a minimum headroom of 4.2 m. Arches over the highway need to be licensed, and physical gateways will not be maintained by the highway authority.

**Speed Restraint within a 20 mph (30 kph) Zone**

In order to influence driver behaviour to keep within the design speed of 20 mph (30 kph), at each location an engineering measure under (a) or (b) below will be required plus in many circumstances a complementary measure under (c) in order to achieve an overall effective measure. Measures to reduce visibility for the driver are not acceptable by themselves. Rumble strips are not an adequate speed restraint measure. Speed restraint measures are to be located at a maximum spacing of 60 m and must be in a different surface material from the rest of the carriageway and well lit. They may be classified as changes in horizontal alignment, changes in vertical alignment or complementary measures.

**(a) Changes in Horizontal Alignment**

**Bends**

These should be tighter than the minimum specified for each road type down to a minimum centre line bend radius of 7.5 m. The deflection should be greater than 45 degrees with a mountable shoulder to enable larger vehicles to overrun.

**Narrows**

The narrowing of the carriageway to 2.7 metres for a length not exceeding 7 metres will make drivers wait for oncoming traffic to pass. A 500 mm mountable shoulder either side will allow service vehicles to negotiate this obstruction. This measure is not appropriate for shared surfaces.

**Chicanes**

To be effective, the lateral displacement of the running lane must be at least 2 metres and the length of the displacement no greater than 10 metres. A reduction of carriageway width to 2 metres at the entrance and exit of the chicane is acceptable, but a mountable shoulder may be necessary to provide a 3.1 metre path for service vehicles. This measure is not appropriate for shared surfaces.
Islands
The island should result in a lateral displacement of the running lane by at least 2 metres. The island may be any shape, subject to the minimum dimensions given below. Mountable shoulders may be used to enable to passage of service vehicles, but the centre of the island should not be overrunnable by any type of vehicle. This measure is not appropriate for shared surfaces.

(b) Changes in Vertical Alignment

Humps
Round-topped humps should be 75 mm high and no longer than 3700 mm. They are not appropriate for shared surfaces or for road Types 1 - 3.

Cushions
On road Type 3, which is likely to be used by buses and emergency services, speed cushions should be used instead of humps. They are designed to allow the wheels of buses and wide wheelbase vehicles to pass either side of the raised area whilst cars have to negotiate the hump. They should be constructed in pairs to the dimensions shown below.

Ramps
Single ramps 100 mm high or successive ramps 50 mm high are appropriate within or at the entrances to shared surfaces.

Speed Tables
A plateau may be created approached by ramps rising 100 mm over a minimum length of 1500 mm. If the road is a bus route the ramps should rise 75 mm at 1 in 15. Unless there is a junction, such a plateau should be no longer than 7 metres. Tactile surfaces should demarcate carriageway and footway for the benefit of the visually impaired. This may be a good way of slowing up traffic for a footpath crossing.
**Table Junction**
A traffic junction may be treated as a plateau approached by ramps as described under ‘Speed Tables’ above. Again, tactile surfaces should demarcate carriageway and footway.

**Shared Surfaces**
Where a shared surface, e.g. a Parking Square, forms an incident along a conventional road, its approaches should be ramped as described under ‘Speed Tables’ above so that the whole shared surface is treated as a plateau. Channels or rows of setts demarcating the vehicle way and a different colour of paving for the perimeter footway will be sufficient indication for the visually impaired.

**(c) Complementary Measures**

**Buildings**
Buildings may form an end-stop to a straight stretch of road, or be angled indicating a change of direction.

They may form a gateway through which the road passes. Used in conjunction with other speed restraints, they can induce drivers to slow up and take extra care.

**Width and Alignment**
Apart from the measures described under ‘Changes in Horizontal Alignment’ above, general variation in the width and alignment of the carriageway can make the driver feel less secure and less able to increase speed.
**Trees and Bollards**
These can be used to hem in chicanes, narrows, changes of direction etc. and make drivers take extra care.

**Surface Materials**
A change in materials or, for example, higher kerbs can serve to emphasise other speed restraint measures and reduce the apparent width of the carriageway. Higher kerbs or retaining walls should be protected by thick planting or railings to keep pedestrians off.

**Junctions**

**Junction Spacing**
For junctions on to county roads, the County Transportation and Development Control Section should be consulted. In the case of residential roads minimum stagger between junctions on opposite sides of a road is X. Minimum stagger between junctions on the same side is 2X. X is to be determined from the following table:-

<table>
<thead>
<tr>
<th>Side Road at Junct.</th>
<th>Main Road at Junction</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>

</tr>
</tbody>
</table>

Side roads joining Type 1 or 2 roads should have no side junctions to other roads within 20 metres of the junction with the major road.

**T-Junctions**
Normally the side turning is off the major traffic flow, but a T-junction which diverts the major traffic flow can be a useful means of reducing speeds.

**Staggered Junctions**
These are possible on Type 4 and lower category roads within a 20 mph (30 kph) zone. The side roads should be staggered by one carriageway width, and right/left staggerers are preferable to left/right as conflicting movements are reduced. Such a junction is possible notwithstanding the junction spacing requirements above.

**Islands and Mini-roundabouts**
These will be more appropriate for Type 4 and higher category roads. The island may be any...
shape, subject to the minimum dimensions given below. Mini-Roundabouts for Type 1 and 2 roads should comply with DTp standards on size and signing.

**Cross-roads**
These should only be used either (a) where two adjacent arms each serve fewer than 25 dwellings or (b) on Type 5 and lower category roads.

**Non-right angle Junctions**
On Type 3 and lower category roads these are allowed down to a limit of 45 degrees, and will accommodate all car turning movements within the carriageway. Below 80 degrees overrun spaces for service vehicles become necessary and instead it may be preferable to ban service vehicle turning movements around the acute angle, provided an alternative route is available and signed in advance.

**Visibility**

**Vehicle/Pedestrian Sight Splays**
These are required where cycleways, road types 7 and 8, house drives, shared private drives, access ways to parking or garage courts, and individual parking spaces and garages are accessed across the footway of a road. Sight splays are to give 1.5 m x 1.5 m clear visibility above a height of 600 mm and may be achieved by splaying back the building or wall abutting the entrance, by setting the building or wall back 1.5 m behind the back edge of the footway, or by widening the entrance by 1.5 m each side. Alternatively various combinations of these measures may be used to achieve the same result.

**Forward Visibility**
At all points on the estate road system, except on road types 7 and 8, sufficient forward visibility must be provided to allow the driver of a vehicle to stop safely. The forward visibility required is related to vehicle speed which is in turn dependent on road alignment. To limit vehicle speeds it is necessary to use bends of small centre line radius and large deflection angle. In a 30 kph (20 mph) zone, the bends will normally be sufficiently tight that the forward visibility line falls within the footway.
Where vehicle speeds are not restricted by road alignment or other speed restraints then a minimum forward visibility of 60m should be provided on the centre of the nearside lane (vehicle speed 50 kph or 30 mph). This would apply to bends with deflection angles less than 30° with a centre line radius of 75m or more.

For bends with deflection angles over 30° and centre line radii of less than 75m, outside 30 kph (20 mph) zones the graph below should be used to determine forward visibility. The figure obtained from the graph should be rounded to the nearest multiple of 3m.

The construction of the forward visibility curve is shown below.

All new trees should be of slender girth when mature and have a trunk clear of side growth to a height of 1.8 m.
Grass is not precluded from the areas of sight splays, but these areas tend to be small and awkwardly shaped, and consequently expensive to maintain. Within forward visibility curves, ground cover to a height of 600 mm as an alternative to grass is acceptable. Trees may be allowed, but the locations shall be agreed, on site, with the highway authority.

**Junction Visibility**
The normal ‘Y’ distances for sight lines at junctions are those given in the description of each road type, and these ‘Y’ distances are to be used in all cases where the speed of vehicles on the through road at the T-junction is not restricted by road alignment within this ‘Y’ distance.

Where the main road at the T-junction contains, within the ‘Y’ distance, a bend with a deflection angle of over 30° and a centre line radius of less than 75 m, it may be possible for the ‘Y’ distance to be reduced.

**Planting in Sight Splays**
At junctions the sight splay can be divided into two visibility zones.
The type of planting considered suitable within sight splays is set out in the following table:

<table>
<thead>
<tr>
<th>Planting</th>
<th>Zone A</th>
<th>Zone B</th>
</tr>
</thead>
<tbody>
<tr>
<td>Existing Trees</td>
<td>Normally no trees permitted. However in exceptional cases trees may be retained. Final decision to be made on site in consultation with the local highway and planning authorities.</td>
<td>Trees may be retained. Final decision to be made on site in consultation with local highway and planning authorities.</td>
</tr>
<tr>
<td>New Trees</td>
<td>No trees permitted.</td>
<td>Trees may be permitted. The precise location will be agreed with the highway authority.</td>
</tr>
<tr>
<td>Ground Cover</td>
<td>Ground cover permitted providing the plants do not generally exceed 600mm in height when mature.</td>
<td>As for Zone A.</td>
</tr>
</tbody>
</table>

Grass is not precluded from the areas of sight splays, but these areas tend to be small and awkwardly shaped, and consequently expensive to maintain. Within forward visibility curves, ground cover to a height of 600 mm as an alternative to grass is acceptable. Trees may be allowed, but the locations shall be agreed, on site, with the highway authority.

**Turning Bays**
It is desirable to locate entrances to premises or to private drives off the ends of turning bays, in order to discourage parking. On road types 3, 4, 5 and 6 the turning bay size is determined by the expected type and frequency of vehicles manoeuvring.

Any cul-de-sac system off a Type 1 or higher category road is to provide a turning bay of not less than size 2 dimensions. This may be contained within the first road junction off the cul-de-sac. Where very large vehicles are likely to frequent the system, then it may be necessary to incorporate a size 1 turning bay.

On types 4-7 which are side turnings from types 3-7 and which are less than 20 m in length, a size 4 turning bay may be used.
On type 8 where less than 20 m in length a size 5 turning bay will be required. In all other circumstances a size 3 turning bay will be sufficient. This is adequate for turning fire and rescue tenders and pantechnicons. The hatched areas in the diagrams left are required for vehicle overhang and must be included as part of the highway.

They can either be:
(i) in road type 7 combined vehicle/pedestrian area, or
(ii) footway

Further information on the characteristics of vehicles turning may be obtained from DB32 (Residential Roads and Footpaths).

In situations where size 3-5 turning bays would normally be permitted, a turning loop incorporating car parking spaces may instead be used.

**Vertical Clearance**
Vertical clearance of 5.000 m is required over the full width of carriageway plus 500 mm at either side. In the event of a crossfall on the carriageway being greater than 2.5% (1 in 40) the 500 mm dimension will need to be increased to 610 mm on the low side of the carriageway.

The vertical clearance required at the entrance to a type 8 mews is 4.1 m. If clearance is less than 5.000 m, it must be signed. However, if a separate service vehicle access is provided then the clearance at the secondary entrance could be reduced to 2.250 m.

**Gradients**
Where a change in gradient occurs, a vertical curve is required at both summits and valleys for comfort of driving and, at summits, to ensure forward visibility. In the latter case, a forward visibility distance of 33 m to a point 600 mm above the road surface is required within 30 kph (20 mph) zones, and 60 m on 50 kph (30 mph) roads.
Culs-de-sac
Where the end of a cul-de-sac abuts a site for possible future development, the cul-de-sac should be of road type capable of serving the likely future number of dwellings.

House drives
House drives are to meet the back of the footway at right angles, and may not deviate therefrom by more than 10°.

Except in the case of road types 7,8 and parking squares a 1.5 m x 1.5 m sight splay is required behind the footway to give clear visibility above a height of 600 mm to at least 1.800m (see page 70). Vehicular access is not permitted across radius kerbs at junctions.

Bollards
Bollards used to protect buildings and demarcate footways etc. in parking squares should be approximately 1.200 m high and made of cast iron or hardwood.

Kerbs
The design of kerbs should complement the design speed and character of the road. Precise details appear in the Highway Authorities’ specifications.

Lighting
Street lighting should be designed to achieve sufficient illumination to enable safe movement by pedestrians and cyclists, reduce opportunities for crime, and enable drivers to see hazards on the road. Designers should also aim to illuminate the built environment in an attractive way, and to select and position lamp standards so that they enhance rather than detract from the daytime scene.

The highway authority will adopt all lighting to public areas adopted as highways, footpaths or cycleways, but not to private drives, provided the fittings conform to the County Council specification and the whole installation complies with BS5489 pt. 3 or current road lighting standards. In rural locations, Parish Councils may require lower levels of street lighting or none at all.

Mounting Heights
Generally, road types 1-3 require a mounting height of 6 metres and all other roads 5 metres. In the case of lamps fixed to buildings, the mounting height may reduce to 4.7 metres.

Means of Support
Lamps may be mounted on columns or, where buildings abut the back edge of the footway or a shared surface road, may be bracketed off buildings. In such cases care should be taken that light is not thrown into adjacent bedroom windows. Columns will normally be Stainton (Petitjean) NIDD galvanised, but appearance is enhanced if they are supplied polymer-coated in a dark colour. The addition of decorative rings will create the effect of the old cast-iron type of column. Columns should normally be located at the back edge of the footpath, or, in the case of a shared surface, at the back of an adopted recess 1 metre x 1 metre. Where there is a 1 metre pedestrian margin, this may reduce to 0.5 m deep.

Type of Lantern
Rather than low pressure sodium (SOX) lamps, the more controllable high pressure sodium (SON) lamp should be used, which produces a whiter, more pleasant light, and limits upward light pollution. In addition, the highway authority is prepared to adopt a range of more attractive lanterns, including post-top types, provided the developer pays a commuted sum to cover extra maintenance, replacement and energy costs (see “Street Lighting -Approved Selection of Lanterns”, Essex County Council Environmental Services).
**Particular Locations**
Lamp standards should be positioned to illuminate speed restraint features clearly. Post-top amenity lanterns should be considered for squares, footpath/cycle links, etc. where they should be accessible by maintenance vehicles. Lamp standards should not be located within 1 metre of a private drive access.

**Parking, Garage Courts and Servicing**

Car parking should be provided for both residents and visitors at an adequate level and in such locations as to be reasonably convenient, visually inconspicuous, and limit opportunities for car-related crime.

**Standard of Provision of Parking Spaces**

Applicants should consult the parking standards of the local planning authority. In areas where there are road capacity problems, in town centres, Conservation Areas, and where a site is convenient to and well served by public transport, it is appropriate to relax parking standards, but in other cases minimum provision is to be as follows:-

(i) Where the parking space is designated for the sole use of the occupier, the standard for each new dwelling of four or more bedrooms shall be three spaces per dwelling, one or two of which may be in the form of a garage. For all other dwellings, the standard shall be two spaces per dwelling, one of which may be in the form of a garage.

(ii) In the case of shared parking areas of more than six spaces serving 1 or 2 bedroom dwellings, the standard shall be one space per dwelling for the use of residents and in addition 50 per cent of that number for the use of visitors (total 150%). Each shared parking area should contain one parking space capable of use by disabled people, see page 76.

(iii) In the case of sheltered housing for elderly persons, the standard shall be two spaces for the warden’s dwelling and one space for every two residents’ dwellings. At least one of these spaces is to be capable of use by disabled people, see page 76. In the case of nursing homes and other homes with communal facilities, the standard shall be two spaces for every resident staff flat and one space for every four residents’ bedspaces.

For non-residential uses refer to Essex County Council’s ‘Standards for Car Parking in Essex’ or the relevant local planning authority’s standards. It will be appropriate to relax these standards where the clustering of facilities results in multi-purpose trips, where the use of different facilities peaks at different times, where facilities are within walking distance of the majority of users, where the site is convenient to and well served by public transport, where there are road capacity problems, or if the site is located in a town centre or Conservation Area. In public car parks 6 per cent of spaces down to a minimum of 3 spaces should be capable of use by disabled people, see page 76. These spaces should be located no further than 50 m from major destinations such as a post office or supermarket.

**Location of Parking Spaces**
Visitor spaces should be located on or near the road frontage, whilst more flexibility is possible in the location of the residents’ space(s). Visitors’ spaces for communal use may (in the case of road types other than Types 1, 2 or 3 where within 30 metres of a junction), be provided by widening the road to accommodate a row of cars parallel to, at right-angles to, or at an angle to, the kerb. In the latter two cases the footway must be widened by 800 mm to accommodate vehicle overhang. Such groups of spaces will be adopted, but should be limited in size and number so as not to dominate visually.

A parking square may also accommodate a group of visitor parking spaces within the highway domain, as may a turning loop (see page 72). Other solutions will be considered on their merits.
The resident’s space(s) or garage(s) may be located on or near the frontage, but in such a way as not to dominate the street scene, eg. through a carriage arch under the building, placed sideways-on to the frontage, or down a side-way between houses. Residents’ spaces may also be located at the rear of houses, either approached between the houses or from a separate road or drive at the back. In the latter case, care should be taken that the parking space is overlooked from the dwelling served or else within a secure garage so as not to provide an opportunity for theft. Where rear access to individual plots is provided this has the advantage that on-plot parking is then possible for caravans and boat trailers.

Communal parking areas should ideally be located so as not to be unduly conspicuous in the layout. In other words, a continuous row of parked cars in front of a terrace of houses is unacceptable. Preferably the communal parking areas will be broken up and distributed around the layout, with some spaces convenient for visitors on or near the frontage, and others at the side or rear of dwellings. Again, in all cases care should be taken that communal parking areas are overlooked by the kitchen or living room windows of at least some dwellings, or footways in regular use, in order to discourage car-related crime.

In the case of communal parking, it is recognised that the distinction between residents’ and visitor spaces is to some extent an unreal one, in that if there are vacant visitor spaces, residents will be liable to use them. Nevertheless, the principle provides enough flexibility that at least some visitors’ cars or extra residents’ cars can be accommodated.
Parking Space
The minimum size of a parking space is 4.8 m x 2.4 m. When the parking space is sited in front of a garage, the long dimension should be 6 metres so as to allow space to open the garage door. A vehicle/pedestrian sight splay of 1.5 m x 1.5 m (see page 70) will normally require giving clear visibility above a height of 600 mm where the parking space abuts the back edge of footway or highway boundary. Exceptions to this requirement will be garages and parking spaces off road types 7, 8, parking squares and private drives.

Parked spaces between structures may require an increased area for pedestrian movement around the vehicle. The length should be increased by 1 metre and width by 500 mm in such cases. In the case of lay-by parking on the highway, spaces should be 6 m x 2 m where adjoining a footway or 2.4 m where not.

A parking space capable of use by disabled people is one that is either widened to 3.6 m or is adjacent to an area on the same level, eg a lowered footway, containing at least 1.2 m width for getting in and out of vehicles.

Garages
The minimum internal garage size is 4.8 m x 2.4 m. Where a garage door abuts the back edge of a footway or shared surface road, the garage is to be set back sufficiently for the swept path of the door not to obstruct circulation. However it is not to be set back more than 3 m unless a full 6m parking space is provided in front. The use of through garages, with doors front and back, is useful in giving access to the rear curtilage for additional parking and storage.

Communal Parking Courts
Parking spaces should be at least 2.4 m x 4.8 m, and rows should be separated by at least 6 m to allow manoeuvring in and out. It may be desirable for some spaces to be designed to accommodate caravans or boats. One parking space in each parking court should be capable of use by disabled people (see 'Parking Space' above).

Entrance ways to parking courts will be as follows:-
(i) Up to 8 parking spaces, as for shared private drives.
(ii) 9 parking spaces and over, access way to be 4.1 m wide, centreline bend radius 6 m minimum, sight lines as for private drives, headroom 2.5 m.

If access for fire tenders is required, see relevant paragraph on the next page. Apart from small groups of visitor parking spaces on or near the frontage, parking courts should be well enclosed by buildings or walls to reduce their intrusiveness, but at the same time overlooked by at least some dwellings or footways in regular use, in order to discourage car-related crime. The incorporation of tree and shrub planting will soften the effect and reduce the apparent size of parking courts, as will the use of more attractive surface materials, such as tar spray and pea shingle dressing, concrete or clay block paving, granite or concrete setts, stable blocks and cobbled edges. Fences enclosing parking courts are vulnerable to vehicle impact and should not be used. Walls are to be used, and where used at the ends of parking spaces should be protected by a kerb set 600 mm into the parking space.
courts will need to be recessed for most types of car to be able to manoeuvre properly. Sufficient space and gullies should be provided for car washing.

Entrance ways are to be as for parking courts, but headroom may reduce to 2.1 m provided fire tender access is not required.

**Servicing**
The adoptable road standards are designed to allow service vehicles up to pantechinicon size to reach all parts of the residential road system (but see page 64). Refuse collection vehicles must be able to reach within 25 metres of all bin collection points (but see page 52).

**Access for Fire Tenders**
Under Building Regulation B5, access for fire tenders is required to a point not further than 45m from all parts of the ground floor of any residential building. Any road or private drive forming part of such a fire access way must be no less than 3.7 m wide between kerbs (though this may reduce to 3.1 m for a gateway or similar short narrowing), and should have a minimum centreline bend radius of 6.55 m* (or 7.75 m* if enclosed by walls) and headroom of 3.7 m. The access way including manholes etc should be capable of carrying a 12.5 tonne vehicle though structures such as bridges should have a minimum carrying capacity of 17 tonnes. A cul-de-sac which is more than 20 m long must have a turning head of at least Size 3. Where there are flats of more than four storeys there are additional access requirements, for which see the Building Regulations and/or the local Building Control authority.

Fire access will normally be to the front of dwellings, but rear access is acceptable provided it is clearly signed and the dwellings are also numbered from that side.

**Car-Free Zones**
In order to reduce traffic and its detrimental effect on the environment, and the amount of space given over to car parking, planning authorities may designate car-free residential zones. These will normally be developments in or near the centre of large towns where a wide range of facilities, employment and access to public transport is available within walking distance of the home. In this situation residents are likely to be prepared to sacrifice the benefits of car ownership in exchange for the proximity and convenience of the location.

Residents of car-free zones will have to enter into a covenant on the purchase or tenancy of their dwelling that they will not drive a vehicle within one mile of the centre of the zone. Thus even a resident parking his or her vehicle in a street near the zone would be in breach of the covenant though he or she would not be precluded from garaging a vehicle some distance away. Car-free zones are only likely to be workable for developments consisting of flats or small houses with small or communally managed gardens, and in areas where main streets in the vicinity have parking restrictions.

As the purpose of a car-free zone is the exclusion of private vehicles, there should be no parking provision either on or off the highway for either residents or visitors. However, provision must be made for access to within reasonable proximity of most dwellings for emergency services and deliveries. The street system should consist of an overall paved surface that reads as ‘pedestrian’ and thus discourages vehicular traffic, e.g. square paving slabs, interlocking clay block paving, granite or artificial sets, stable blocks or tar spray and shingle dressing. Entrances to the zone should be over a dropped kerb from access streets leading to the zone. There should be a ‘No Entry’ sign at each entrance to the zone reading ‘Except for Deliveries’. Up to within 45m of the furthest part of the ground floor of the furthest dwelling the street system of the zone should be laid out to the requirements in the preceding paragraph for access for fire tenders, i.e. a minimum width of 3.7m, minimum centreline bend radius of 6.55m, load bearing capacity of 12.5 tonnes, and no reversing necessary for a distance longer than 20m.

However the vehicle path thus determined should not be marked out, the paving being laid between the face of buildings, walls, garden boundaries, etc. and designed primarily for pedestrian and cycle use. The paved area should contain trees and other suitable obstacles that discourage parking but still allow a free path for delivery and emergency vehicles.

The pedestrian street system should link up with other streets outside the zone and offer a choice of routes through the area, but the highway authority will only adopt those streets that form part of a main pedestrian or cycle through route.

See Case Study 14 on page 102 for an example of the application of these principles.

---

* This is expressed in the Building Regulations as a turning circle of 16.8m and 19.2m respectively
It is the purpose of the following case studies to show how the principles of this Guide can be put into practice in the design of the layout of a number of sites with differing requirements and characteristics. These should not be regarded as stereotype solutions to be copied, but as demonstrations of the application of the approach advocated by this Guide.

A number of small areas of development are demonstrated showing different approaches:

1. An informal urban street.
2. A variable-width street with the variety of frontage associated with the traditional village.
3. A formal street of 2-3 storey houses and on-street parking.
4. A set-piece of buildings at a major entrance to the site.
5. A piece of urban layout with variable-width roads and a 'market square' focus.
6. A large, landscaped square.
8. A formal square.
10. A village-type, tree-lined street with housing of mixed densities.
11. A pedestrian street.
12. A small mews cul-de-sac.
14. A 'brownfield' site development incorporating mixed uses.

These case studies may be viewed in isolation as potential small infill developments, or they may be viewed as the jigsaw pieces of a much larger development. Since one of the aims of this Guide is to demonstrate principles for the structuring of large developments the individual case studies are also combined here into a large layout not untypical in extent of the substantial peripheral or freestanding developments that have been started in recent years.

Apart from showing the overall framework of the large development, this example also includes a District Centre (see “The Core” on page 11).
Large development comprising case studies

- Public open space
  - Major access point to development and town centre
  - Three storey set piece flats
  - Shopping and community centre incorporating superstore and mixed use
  - Large landscaped formal square
  - Existing woodland preserved
  - ‘Arcadian’ houses face onto woodland and perimeter planting
  - By-pass dual carriageway forms boundary to development scheme
  - Formal composition of 3 storey buildings facing school playing fields
  - Key three storey building at entry points to development
  - Wide landscape margin between houses and main road
  - Informal village green
  - 6m wide plus verges. Start of Avenue tree lined road links all of scheme
  - Entrance to scheme over water feature of balancing pond

- Variable width road incorporates parking
- Tree lined avenue 6m carriageway links all sections of scheme
- Village street
- Boulevard planning
- Set piece three storey scheme at entrance
- Large landscaped foreground to development
- Low density arcadia faces open space
- Major open space between new and existing development
- To existing comprehensive school
- Primary school 2
- Neighbourhood public house and shop
- Large key building in landscape
- Existing development
- Major open space between new and existing development
- To existing comprehensive school
- Primary school 2
- Neighbourhood public house and shop
- Large key building in landscape
- Entrance to scheme over water feature of balancing pond
Location of Case Studies

- **Case study 1**: Informal urban street
  - Key case study showing achievable spatial relationship between urban housing and road space access and parking

- **Case study 2**: Village street
  - Variable width houses all attached but of wide variety of frontages and designs

- **Case study 3**: Urban street
  - Urban 2 & 3 storey scheme incorporating on-street parking for visitors and rear parking and garaging

- **Case study 4**: Major entry point to development area
  - Three storey flats

- **Case study 5**: Urban layout
  - Incorporating variable width roads and market square parking

- **Case study 6**: Large landscaped square
  - With three storey houses

- **Case study 7**: Boulevard layout
  - With urban squares at either end of formal sequences of detached houses

- **Case study 8**: Formal square
  - With detached houses
  - Central space planted and incorporating visitor parking

- **Case study 9**: Village green
  - Square of housing around a green with a variety of routes across. Large house/flats command the end of green

- **Case study 10**: Urban village
  - Wide street, tree lined on-street parking
  - Also formal and arcadian housing

- **Case study 11**: Pedestrian street

- **Case study 12**: Mews court
  - Small urban courtyard scheme

- **Case study 13**: Arcadia

- **Case study 14**: Existing development
Case study 1

Informal urban street

Variety of houses mainly wide frontage shallow plan, mainly joined together, some without on-plot parking. Most houses front back edge of footway without front gardens. This is a practical and flexible format for the typical residential layout at urban densities (8 dwellings per acre, 20 dwellings per hectare and above).
Case study 1

Ground floor plan

First floor plan

Second floor plan
Case study 1
Informal urban street

Typical unsatisfactory layout using standard detached house types
Conventional developer’s solution for the same site as comparison using same size houses. Frontage dominated by parked cars. Fragmented street scene due to useless narrow gaps between detached houses. Smaller private gardens due

Developer’s house types
(higher proportion of narrow frontage deep plan types)

Ground floor

First floor
Variety of houses mainly joined together, some without on-plot parking. This is acceptable as street is widened at certain points to accommodate street parking. All houses front back edge of footway without front gardens.
Case study 3
Urban 2 and 3 storey housing

All houses joined together in terraces. Two crescents of 3 storey town houses as focus. Street widened to accommodate on-street parking.

See Case Study location plan on page 81
Case study 4
Major entry point

3 storey flats arranged as a composition centred on traffic roundabout giving access to residential area from local distributor or county road.

- Type 3 road, or Type 2 if serving neighbourhood superstore with lorry traffic.
- 2 storey housing
- Entrance on side away from main road to prevent on-street parking
- Garaging and parking to flats
- 3 storey flats
- Communal walled garden
- Focal feature on roundabout
- Tree-planted verges
- 2 storey housing
- Anti-noise bund if heavily trafficked road
- Garaging and parking to flats

See Case Study location plan on page 81
Focuses on informal ‘market square’ paved between fronts of buildings. ‘Back lanes’ give access to rear of some plots and provide extra parking and garaging as well as serving their own frontage development.
Case study 6
Large landscaped square

3 storey town houses in terraces required in order to enclose large landscaped space
Parking and garaging on-plot and provided through carriage arches to prevent car-dominated frontage

See Case Study location plan on page 81

Adjoining Arcadian layout
Private garden areas may reduce due to facing public open space
Carriage arches
Garages and parking spaces to rear
Front gardens possible
Type 6 minor access way 4.1m wide, 1.35m overrunnable footway
Table junction
Generous tree planting
Type 4 road, 4.8m wide with 1.5m footway
No footway required around open space
Other landscaped areas link to provide wildlife corridor
Case study 7
Boulevard planning

Detached houses designed to a single architectural theme set in a formal plan. Structural tree and hedge planting reinforces the concept. Urban design sequence starts and finishes with strong urban forms (Formal Squares).

See Case Study location plan on page 81
Case study 8
Formal square (detached houses)

Detached houses designed to a single architectural theme set in a formal plan.

- Houses linked by gateways
- Front gardens possible
- Pinch point of buildings at entrance to square
- Formal tree planting in square
- All garaging between and to rear of houses
- Corner-filling houses
- Central feature
- Road type 4 - 4.8m wide with 1.5m footways right angle bends act as speed restraint in square

See Case Study location plan on page 81.
Variety of houses, mainly joined together, with parking provided on-plot or communally at rear, arranged to provide continuity of frontage. Some houses front back edge of footway, some have front gardens. Garden areas may reduce due to fronting on to large public open space.

Network of Type 4 4.8m roads, shingle finish, no kerbs. Footways only on housing frontages at perimeter of green.

- Houses supervising parking court
- 3 storey elements to give variety to perimeter of green
- Small visitor parking area on green
- 3 storey formal building dominating green (‘country house’)
- Carriage arches for some accesses to maintain continuity of frontage
- Cart lodge parking on axis of ‘country house’
Case study 10

Urban village

Variety of houses, mainly joined together with parking provided on-plot or communally at rear, arranged to provide maximum continuity of frontage to urban spaces. Except around small green, all houses front back edge of footway without front gardens.

Parking courts
Houses form end stop to street
Small green - fragmented building frontage but strong enclosure by trees

Garage court with studio flats over garages
Visitor parking at right angles to carriageway under trees
Avenue tree planting
Flats with communal garden and parking (shown in more detail in Appendix E, p.113)
3 storey flats dominate street and green
Carriage arches to maintain continuity of frontage
Adjacent Arcadian housing
3 storey town houses at intervals

See Case Study location plan on page 81
Case study 11
Pedestrian spine street

Attractive pedestrian scale street continuously enclosed and fronted by houses. Parking and garaging to rear. Not having to accommodate vehicles means the street space can narrow to give a height of buildings to street width ratio characteristic of narrow streets in historic towns and villages. All houses within Fire and Rescue hosereel distance of road.

See Case Study location plan on page 81
Case study 12
Mews court

Visitors parking in square
Maintain frontage continuity of through road
Taller building emphasises central axis
Carriage arches maintain continuity of frontage
Enclosed corners to square
No sightsplays required at vehicle accesses within Mews Court

Residents parking beneath or behind buildings
Mews court less than 20m long

1.5 x 1.5m sightsplays
Enclosure by buildings or 1.8m walls up to 8m back from footway
Type 8 Mews Court 4.8m wide

Mews court more than 20m long

Type 8 Mews Court 4.8m wide
Overall paving in turning area, gaps for trees

See Case Study location plan on page 81

1.5 x 1.5m sightsplays
Ramp 6m back from footway
Size 5 turning head
Parking court

Size 3 turning head
Overall paving in turning area, gaps for trees
Parking court
Case study 13

Arcadia

Layout at density not exceeding 8 houses per hectare (3 houses per acre). Houses sufficiently widely spaced to allow existing and new landscape to dominate. Meandering road alignment. Hedge and hedge-bank boundaries, including front boundaries to roads.
Higher density area, in or near the centre of a large town. Wide range of existing facilities, employment and access to public transport within walking distance. Car-free zone covering most of the area (see page 81).
